How to use this guide

This manual is intended for administrators responsible for installing, configuring, and maintaining multiple interconnected or replicated Perforce services.

This guide assumes familiarity with *Helix Core Server Administrator Guide: Fundamentals*.

This section provides information on typographical conventions, feedback options, and additional documentation.

Syntax conventions

Helix documentation uses the following syntax conventions to describe command line syntax.

Notation	Meaning
<code>literal</code>	Must be used in the command exactly as shown.
<i>italics</i>	A parameter for which you must supply specific information. For example, for a <i>serverid</i> parameter, supply the ID of the server.
<code>[-f]</code>	The enclosed elements are optional. Omit the brackets when you compose the command.
...	<ul style="list-style-type: none">Repeats as much as needed:<ul style="list-style-type: none"><code>alias-name [[\$(arg1) ... [\$(argn)]] =transformation</code>Recursive for all directory levels:<ul style="list-style-type: none"><code>clone perforce:1666 //depot/main/p4... ~/local-repos/main</code><code>p4 repos -e //gra.../rep...</code>
<code>element1 element2</code>	Either <i>element1</i> or <i>element2</i> is required.

Feedback

How can we improve this manual? Email us at manual@perforce.com.

Other documentation

What's new in this guide

This section provides a summary with links to topics in this Guide. For a complete list of what's new in this release, see the [Release Notes](#).

2018.2 release

Various bug fixes as mentioned in the [Release Notes](#).

2018.1 release

To help the standby server stay as current as possible with the master server, consider using the configurable that enables writing to the device on which the standby server's active journal would be located. See the mention of the `rpl.journalcopy.location` configurable at "Configuring a read-only replica" on page 40.

2017.2 release

Complete replication for graph depot archives

Edge servers support syncing file content from graph depots. Replication supports graph depots that contain pack files, loose files, or a mixture of the pack files and loose files.

New content can be pushed by using the Git Connector or committed with `p4 submit` or `p4 merge`.

For information about depots of type graph, see:

- [Working with depots of type graph](#) in the P4 Command Reference.
- [Overview](#) in the Helix4Git Administrator Guide.

Helix Core Server Control (p4dctl) has moved

The appendix formerly named **Helix Versioning Engine Control (p4dctl)**, which was both in this guide (volume 2 of the "Helix Versioning Engine Administrator Guide") and in the volume 1, "Helix Versioning Engine Administrator Guide: Fundamentals" (volume 1) is now exclusively in volume 1 at <https://www.perforce.com/perforce/doc.current/manuals/p4sag/#P4SAG/appendix.p4dctl.html>.

Introduction to federated services

Helix Core Server Administrator Guide: Fundamentals explains how you create, configure, and maintain a single Helix Core Server. Small organizations often find a single server is adequate to meet user needs. However, as the business grows and usage expands in scale and geography, many organizations deploy a more powerful server-side infrastructure.

Architecture	Advantage	Disadvantage
<p>"Helix Proxy" on page 107</p>  <p>The diagram illustrates the Helix Proxy architecture. At the center is a 'Master' node, represented by a stack of disks with a star, labeled 'Master with both versioned files and metadata'. It is connected via 'WAN' to several 'Proxy' nodes. One proxy node is labeled 'Proxy with a cache of versioned files' and includes 'p4p /var/proxy1/root'. Another proxy node is labeled 'p4d /p4/1/root'. Clients are shown in USA and France, connected to their respective proxy nodes.</p>	<ul style="list-style-type: none"> ■ easy to install, configure, and maintain ■ improves performance by caching frequently transmitted file revisions ■ reduces demand on the Performance service and the network over which it runs ■ no need to back up the proxy cache ■ especially beneficial with larger files 	<ul style="list-style-type: none"> ■ not optimal for syncing large numbers of small files <div style="border: 1px solid green; padding: 5px; margin-top: 10px;"> <p>Tip</p> <ul style="list-style-type: none"> ■ A proxy cannot be deployed in front of a forwarding replica ■ See the Support Knowledgebase article on Proxy Performance. </div>

Architecture	Advantage	Disadvantage
<p data-bbox="245 289 537 321">"Helix Broker" on page 87</p>  <p data-bbox="245 338 976 1045">The diagram illustrates the Helix Broker architecture. At the top, three clients are shown: 'Client in USA' (with a US flag), 'Client in France' (with a French flag), and 'Client in Japan' (with a Japanese flag). Each client is connected to a corresponding proxy: Proxy1, Proxy2, and Proxy3. These proxies connect to a central 'p4broker on a single P4PORT'. The p4broker is divided into two functional blocks: one that 'routes READ commands to the replica' and another that 'routes WRIT commands to the'. Below the p4broker, two 'read-only REPLICATION' servers are shown, each processing 'read' commands. The servers are connected to each other, indicating a replication relationship.</p>	<ul data-bbox="1040 296 1182 1297" style="list-style-type: none">■ rule-based load distribution that typically frees the master from "read commands"■ well-suited for builds from the read-only replica■ facilitates swapping the servers for a checkpoint or upgrade <p data-bbox="997 1318 1182 1373">Tip</p>	<ul data-bbox="1255 296 1398 1010" style="list-style-type: none">■ broker layer causes some overhead in network performance■ see the Support Knowledgebase article, "Using P4Broker to redirect read-only commands".

Architecture	Advantage	Disadvantage
	<p>Can display a friendly "Down for Maintenance" message when the p4d process is offline for maintenance or failover (as opposed to a TCP connect error)</p>	

Architecture	Advantage	Disadvantage
<p>Forwarding replica</p>  <p>The diagram illustrates the Forwarding replica architecture. At the center is the Master Server in France, which acts as the single-source-of-truth for metadata, files, and workspace data. It is connected via WAN to two Forwarding Replicas: one in the USA and another in an unspecified location. The USA Forwarding Replica has a Local cache of files and metadata, can be used as a warm standby. Clients are shown: Client in USA connected to the USA Forwarding Replica, Client in France connected to the Master Server, and another Client in (partially visible) connected to the other Forwarding Replica.</p>	<ul style="list-style-type: none">■ customizable filtering	<ul style="list-style-type: none">■ "write" commands are slower because local metadata must be pulled from the master■ requires machine provisioning and administration. See "Configuring a forwarding replica" on page 50. <p>Tip Starting with 2018.2, we recommend a standby server with <code>rpl.journalcopy.location=1</code> for high availability and disaster recovery.</p>

Architecture	Advantage	Disadvantage
	<ul style="list-style-type: none"> ■ supports "daisy chaining" to additional sites. For example, a site in the Philippines might forward to a site in Taiwan that forwards to a site in Japan that forwards to the Master in France. This alternative to directly connecting each Asian site to Europe: <ul style="list-style-type: none"> • reduces the metadata replication load on the master server 	

Architecture	Advantage	Disadvantage
<p>"Commit-edge" on page 64</p>  <p>The diagram illustrates a federated architecture with a central Commit Server in France (marked with a star) connected via WAN to Edge Servers in USA and Japan. Clients in USA and France are connected to their respective Edge Servers. A text box notes that local shelves cannot be used as a warm standby.</p>	<ul style="list-style-type: none"> ■ best performance overall because most commands are local 	<ul style="list-style-type: none"> ■ cannot be used as a warm standby ■ requires machine provisioning and administration, including backups of each edge

Tip
 For a more detailed summary of replica server types, see the Support Knowledgebase article, "Replica Types and Use Cases".

Other types of federated architecture

A federated architecture might also include servers dedicated to centralized authorization and changelist numbering. See "Configuring centralized authorization and changelist servers" on page 20.

Setting up federated services

This section describes some of the issues that administration must address in setting up a federated environment.

General guidelines	15
Authenticating users	16
Connecting services	16

General guidelines

Follow these guidelines to simplify the administration and maintenance of federated environments:

- Assign a server ID to every server
 - it is best if the serverID is the same as the server name
 - use the `p4 server` command to identify each server in your network.
- Assign a service user name to every server by using the `p4 server` command
 - this simplifies the reading of logs and provides authentication and audit trails for inter-server communication
 - each service user name should be unique
 - assign service users strong passwords (see "strong passwords" at [p4 password](#))
- Enable structured logging on all your services. Doing so:
 - simplifies debugging and analysis
 - is one of the prerequisites for using the `p4 journaldbchecksums` command to verify the integrity of a replica
- Configure each server to reject operations that reduce its disk space below the limits defined by that service's `fileSYS.*.min` configurables, such as `fileSYS.depot.min`.
- Monitor the integrity of your replicas by using the `integrity.csv` structured server log and the `p4 journaldbchecksums` command. See "[Verifying replica integrity](#)" on [page 59](#).

Authenticating users

Users must have a ticket for each server they access in a federated environment. The best way to handle this requirement is to set up a single login to the master, which is then valid across all replica instances. This is particularly useful with failover configurations, when you would otherwise have to re-login to the new master server.

You can set up single-sign-on authentication using two configurables:

- Set `auth.id` to the same value for all servers participating in a distributed configuration.
- Enable `rpl.forward.login` (set to `1`) for each replica participating in a distributed configuration.

There might be a slight lag while you wait for each instance to replicate the `db.user` record from the target server.

Connecting services

Services working together in a federated environment must be able to authenticate and trust one another.

- When using SSL to securely link servers, brokers, and proxies together, each link in the chain must trust the upstream link.

- It is best practice (and mandatory at security level 4) to use ticket-based authentication instead of password-based authentication. This means that each service user for each server in the chain must also have a valid login ticket for the upstream link in the chain.

Managing trust between services

The user that owns the server, broker, or proxy process is typically a service user. As the administrator, you must create a `P4TRUST` file on behalf of the service user by using the `p4 trust` command. By default, a user's `P4TRUST` file resides in that user's home directory with `.p4trust` as the file name.

See the "[Communicating port information](#)" topic in the *Helix Core Server Administrator Guide: Fundamentals*.

Managing tickets between services

When linking servers, brokers, and proxies together, each service user must be a valid service user at the upstream link, and it must be able to authenticate with a valid login ticket. Follow these steps to set up service authentication:

1. On the upstream server, use `p4 user` to create a user of type `service`, and `p4 group` to assign it to a group that has a long or `unlimited` timeout.
Use `p4 passwd` to assign the service user a strong password.
2. On the downstream server, use `p4 login` to log in to the master server as the newly-created service user, and to create a login ticket for the service user that exists on the downstream server.
3. Ensure that the `P4TICKETS` variable is correctly set when the user (often a script or other automation tool) invokes the downstream service. This enables the downstream service to correctly read the ticket file and authenticate itself as the service user to the upstream service.

Managing SSL key pairs

When configured to accept SSL connections, all server processes (`p4d`, `p4p`, `p4broker`), require a valid certificate and key pair on startup.

The process for creating a key pair is the same as it is for any other server: set `P4SSLDIR` to a valid directory with valid permissions, and use the following commands to generate pairs of `privatekey.txt` and `certificate.txt` files, and make a record of the key's fingerprint.

- Server: use `p4d -Gc` to create the key/certificate pair and `p4d -Gf` to display its fingerprint.
- Broker: use `p4broker -Gc` to create the key/certificate pair and `p4broker -Gf` to display its fingerprint.
- Proxy: use `p4p -Gc` to create the key/certificate pair and `p4p -Gf` to display its fingerprint.

You can also supply your own private key and certificate. See "[Using SSL to encrypt connections to a Helix Server](#)" in *Helix Core Server Administrator Guide: Fundamentals*.

Backing up and upgrading services

Backing up and upgrading services in a federated environment involve special considerations. This section describes the issues that you must resolve in this environment.

Backing up services	18
Upgrading services	19

Backing up services

How you back up federated services depends upon the service type:

Broker	<ul style="list-style-type: none">■ stores no data locally■ back up its configuration file manually
Proxy	<ul style="list-style-type: none">■ requires no backups and automatically rebuilds its cache of data if files are missing■ contains no logic to detect when disk space is running low. Periodically monitor your proxy to ensure it has sufficient disk space.

Server	<ul style="list-style-type: none"> ■ Follow the backup procedures described in the Helix Core Server Administrator Guide: Fundamentals. If you are using an edge-commit architecture, both the commit server and the edge servers must be backed up. Use the instructions given in "Backup and high availability/disaster recovery (HA/DR) planning" on page 83. ■ Backup requirements for replicas that are not edge servers vary depending on your site's requirements. ■ Consider taking checkpoints offline so that your users are not blocked from accessing the primary server during lengthy checkpoint operations. See the Support Knowledge Base articles on "Offline Checkpoints" and Taking Checkpoints on Edge and Replica Servers, especially the section on "Detecting Coordinated Checkpoint Completion" ■ Although a checkpoint (<code>p4d -jc</code>) is NOT supported on an edge or replica server, you CAN take a checkpoint dump on an edge or replica server (<code>p4d -jd</code>). See the Helix Core Server (p4d) Reference. ■ Maintaining journals: <ul style="list-style-type: none"> • on edge servers is a best practice • on replica servers is optional, and you can disable such journals by using <code>p4d -J off</code> ■ You can have triggers fire when the journal is rotated on an edge or replica server. See "Triggering on journal rotation" in Helix Core Server Administrator Guide: Fundamentals. ■ Journal rotation on a replica or edge server begins AFTER the master has completed its journal rotation
--------	---

Upgrading services

Servers, brokers, and proxies must be at the same release level in a federated environment. When upgrading use a process like the following:

1. Shut down the furthest-upstream service or commit server and permit the system to quiesce.
2. Upgrade downstream services first, starting with the replica that is furthest downstream, working upstream towards the master or commit server.
3. Keep downstream services stopped until the server immediately upstream has been upgraded.

Configuring centralized authorization and changelist servers

There are cases where rather than using federated services you want to use a collection of servers that have a shared user base. In this situation, you probably want to use specialized servers to simplify user authentication and to guarantee unique change list numbers across the organization. The following subsections explain how you create and use these servers: **P4AUTH** for centralized authentication and **P4CHANGE** to generate unique changelist numbers.

Centralized authorization server (P4AUTH)	20
Centralized changelist server (P4CHANGE)	23

Centralized authorization server (P4AUTH)

If you are running multiple Helix Servers, you can configure them to retrieve protections and licensing data from a *centralized authorization server*. By using a centralized server, you are freed from the necessity of ensuring that all your servers contain the same users and protections entries.

Note

When using a centralized authentication server, all outer servers must be at the same (or newer) release level as the central server.

If a user does not exist on the central authorization server, that user does not appear to exist on the outer server. If a user exists on both the central authorization server and the outer server, the most permissive protections of the two lines of the protections table are assigned to the user.

You can use any existing Helix Core Server in your organization as your central authorization server. The license file for the central authorization server must be valid, as it governs the number of licensed users that are permitted to exist on outer servers. To configure a Helix Core Server to use a central authorization server, set **P4AUTH** before starting the server, or specify it on the command line when you start the server.

If your server is making use of a centralized authorization server, the following line will appear in the output of **p4 info**:

```
...
Authorization Server: [protocol:]host:port
```

Where **[protocol:]host:port** refers to the protocol, host, and port number of the central authorization server. See ["Specifying hosts" on page 93](#).

In the following example, an outer server (named **server2**) is configured to use a central authorization server (named **central**). The outer server listens for user requests on port 1999 and relies on the central server's data for user, group, protection, review, and licensing information. It also joins the protection table from the server at **central:1666** to its own protections table.

For example:

```
$ p4d -In server2 -a central:1666 -p 1999
```

Note

On Windows, configure the outer server with `p4 set -S` as follows:

```
C:\> p4 set -S "Outer Server" P4NAME=server2
C:\> p4 set -S "Outer Server" P4AUTH=central:1666
C:\> p4 set -S "Outer Server" P4PORT=1999
```

Important

To avoid configuration problems, the value of `serverID` should always match the value of `P4NAME` if both are set. We recommend setting `serverID`, but support `P4NAME` for backward compatibility.

When you configure a central authorization server, outer servers forward the following commands to the central server for processing:

Command	Forwarded to auth server?	Note
<code>p4 group</code>	Yes	Local group data is derived from the central server.
<code>p4 groups</code>	Yes	Local group data is derived from the central server.
<code>p4 license</code>	Yes	License limits are derived from the central server. License updates are forwarded to the central server.
<code>p4 passwd</code>	Yes	Property values are derived from the central server.
<code>p4 property</code>	Yes	For example, if two Swarm instances use the same auth server, updating one instance can update the other instance.
<code>p4 review</code>	No	The default user named <code>remote</code> must have access to the central server. However, best practice is to create "Service users" on page 33 and not use the default user named <code>remote</code> . See Restricting access to remote depots in Helix Core Server Administrator Guide: Fundamentals.
<code>p4 reviews</code>	No	The default user named <code>remote</code> must have access to the central server. However, best practice is to create "Service users" on page 33 and not use the default user named <code>remote</code> . See Restricting access to remote depots in Helix Core Server Administrator Guide: Fundamentals.

Command	Forwarded to auth server?	Note
<code>p4 user</code>	Yes	Local user data is derived from the central server.
<code>p4 users</code>	Yes	Local user data is derived from the central server.
<code>p4 protect</code>	No	The local server's protections table is displayed if the user is authorized (as defined by the combined protection tables) to edit it.
<code>p4 protects</code>	Yes	Protections are derived from the central server's protection table as appended to the outer server's protection table.
<code>p4 login</code>	Yes	Command is forwarded to the central server for ticket generation.
<code>p4 logout</code>	Yes	Command is forwarded to the central server for ticket invalidation.

Limitations and notes

- All servers that use **P4AUTH** must have the same Unicode setting as the central authorization server.
- Setting **P4AUTH** by means of a `p4 configure set P4AUTH=[protocol:]server:port` command requires a restart of the outer server.
If you need to set **P4AUTH** for a replica, use the following syntax:
`p4 configure set ServerName#P4AUTH=[protocol:]server:port`
- If you have set **P4AUTH**, no warning will be given if you delete a user who has an open file or client.
- To ensure that `p4 review` and `p4 reviews` work correctly, you must enable remote depot access for the service user (or, if no service user is specified, for a user named **remote**) on the central server.
Note: There is no **remote** type user; there is a special user named **remote** that is used to define protections for a remote depot.
- To ensure that the authentication server correctly distinguishes forwarded commands from commands issued by trusted, directly-connected users, you must define any IP-based protection entries in the Perforce service by prepending the string "proxy-" to the `[protocol:]host:port` definition.

Important

Before you prepend the string **proxy-** to the workstation's IP address, make sure that a broker or proxy is in place.

- Protections for non-forwarded commands are enforced by the outer server and use the plain client IP address, even if the protections are derived from lines in the central server's protections table.

Centralized changelist server (P4CHANGE)

By default, Helix Servers do not coordinate the numbering of changelists. Each Helix Core Server numbers its changelists independently. If you are running multiple servers, you can configure your servers to refer to a *centralized changelist server* from which to obtain changelist numbers. Doing so ensures that changelist numbers are unique across your organization, regardless of the server to which they are submitted.

Note

When using a centralized changelist server, all outer servers must be at the same (or newer) release level as the central server.

To configure Helix Server to use a centralized changelist server, set `P4CHANGE` before starting the second server, or specify it on the `p4d` command line with the `-g` option:

```
$ p4d -In server2 -g central:1666 -p 1999
```

Note

On Windows, configure the outer server with `p4 set -S` as follows:

```
C:\> p4 set -S "Outer Server" P4NAME=server2
C:\> p4 set -S "Outer Server" P4CHANGE=central:1666
C:\> p4 set -S "Outer Server" P4PORT=1999
```

Important

To avoid configuration problems, the value of `serverID` should always match the value of `P4NAME` if both are set. We recommend setting `serverID`, but support `P4NAME` for backward compatibility.

In this example, the outer server (named `server2`) is configured to use a centralized changelist server (named `central`). Whenever a user of the outer server must assign a changelist number (that is, when a user creates a pending changelist or submits one), the centralized server's next available changelist number is used instead.

There is no limit on the number of servers that can refer to a centralized changelist server. This configuration has no effect on the output of the `p4 changes` command; `p4 changes` lists only changelists from the *currently* connected server, regardless of whether it generates its own changelist numbers or relies on a centralized changelist server.

If your server is making use of a centralized changelist server, the following line will appear in the output of `p4 info`:

```
...  
Changelist Server: [protocol:]host:port
```

Where `[protocol:]host:port` refers to the protocol, host, and port number of the centralized changelist server.

Verifying shelved files

The verification of shelved files lets you know whether your shelved archives have been lost or damaged.

If a shelf is local to a specific edge server, you must issue the `p4 verify -S` command on the edge server where the shelf was created. If the shelf was promoted, run the `p4 verify -S` on the commit server.

You may also run the `p4 verify -S t` command on a replica to request re-transfer of a shelved archive that is missing or bad. Re-transferring a shelved archive from the master only works for shelved archives that are present on the master; that is, for a shelf that was originally created on the master or that was promoted if it was created on an edge server.

Helix Server replication

This topic assumes you have read the ["Introduction to federated services"](#) on page 9.

Replication is the duplication of server data from one Helix Core Server to another Helix Core Server, ideally in real time. You can use replication to:

- Provide warm standby servers
A replica server can function as an up-to-date warm standby system to be used if the master server fails. Such a replica server requires that both server metadata and versioned files are replicated.
- Reduce load and downtime on a primary server
Long-running queries and reports, builds, and checkpoints can be run against a replica server, reducing lock contention. For checkpoints and some reporting tasks, only metadata needs to be replicated. For reporting and builds, replica servers need access to both metadata and versioned files.
- Provide support for build farms
A replica with a local (non-replicated) storage for client workspaces (and their respective have lists) is capable of running as a build farm.
- Forward write requests to a central server
A forwarding replica holds a readable cache of both versioned files and metadata, and forwards commands that write metadata or file content towards a central server. A forwarding replica offers a blend of the functionality of the Helix Proxy with the improved performance of a replica. (See ["Configuring a forwarding replica"](#) on page 50.)

Combined with a centralized authorization server, Helix Server administrators can configure the Helix Broker to redirect commands to replica servers to balance load efficiently across an arbitrary number of replica servers. See ["Centralized authorization server \(P4AUTH\)"](#) on page 20 and ["Helix Broker"](#) on page 87.

Note

Most replica configurations are intended for reading of data. If you require read and write access to a remote server, use a forwarding replica, a distributed Perforce service, or the Helix Proxy. See ["Configuring a forwarding replica"](#) on page 50, ["Commit-edge"](#) on page 64 and ["Helix Proxy"](#) on page 107.

Tip

The following Support Knowledgebase articles contain valuable information:

- [Installing a Helix Replica Server](#)
- [Checkpoints in a Distributed Helix environment](#)
- [Taking Checkpoints on Edge and Replica Servers](#)
- [Configuring Checkpoint and Rotated Journal location in Distributed Helix Environments](#)
- [Inspecting replication progress](#)
- [Verifying Replica Integrity](#)
- [How to reseed a replica server](#)
- [Edge Server Meta Data Recovery](#)
- [Failing over to a replica server](#)
- [Edge Servers](#) (differences in behavior of certain commands)

System requirements

- Replica servers should be at the same release as the master server.

Important

See "[Upgrading replica servers](#)" on page 49 and the Support Knowledgebase article, "[Upgrading Replica Servers](#)".

- Replica servers must have the same Unicode setting as the master server.
- Replica servers must be hosted on a filesystem with the same case-sensitivity behavior as the master server's filesystem.
- `p4 pull` (when replicating metadata) does not read compressed journals. The master server must not compress journals until the replica server has fetched all journal records from older journals. Only one metadata-updating `p4 pull` thread can be active at one time.
- The replica server does not need a duplicate license file.
- The master and replica servers must have the same time zone setting.

Note

On Windows, the time zone setting is system-wide.

On UNIX, the time zone setting is controlled by the `TZ` environment variable at the time the replica server is started.

Replication basics

Replication of Helix Servers depends upon several commands and configurables:

Command or Feature	Typical use case
<code>p4 pull</code>	<p>A command that can replicate both metadata and versioned files, and report diagnostic information about pending content transfers.</p> <p>A replica server can run multiple <code>p4 pull</code> commands against the same master server. To replicate both metadata and file contents, you must run two <code>p4 pull</code> threads simultaneously: one (and only one) <code>p4 pull</code> (without the <code>-u</code> option) thread to replicate the master server's metadata, and one (or more) <code>p4 pull -u</code> threads to replicate updates to the server's versioned files.</p>
<code>p4 configure</code>	<p>A configuration mechanism that supports multiple servers.</p> <p>Because <code>p4 configure</code> stores its data on the master server, all replica servers automatically pick up any changes you make.</p>
<code>p4 server</code>	<p>A configuration mechanism that defines a server in terms of its offered services. To be effective, the <code>ServerID:</code> field in the <code>p4 server</code> form must correspond with the server's <code>server.id</code> file as defined by the <code>p4 serverid</code> command.</p>
<code>p4 serverid</code>	<p>A command to set or display the unique identifier for a Helix Core Server. On startup, a server takes its ID from the contents of a <code>server.id</code> file in its root directory and examines the corresponding spec defined by the <code>p4 server</code> command.</p> <div data-bbox="553 1041 1386 1226" style="background-color: #f9f9f9; padding: 10px; border: 1px solid #ccc;"> <p>Important To avoid configuration problems, the value of <code>serverID</code> should always match the value of <code>P4NAME</code> if both are set. We recommend setting <code>serverID</code>, but support <code>P4NAME</code> for backward compatibility.</p> </div>
<code>p4 verify -t</code>	<p>Causes the replica to schedule a transfer of the contents of any damaged or missing revisions.</p> <p>The command reports <code>BAD!</code> or <code>MISSING!</code> files with <code>(transfer scheduled)</code> at the end of the line.</p> <p>For the transfer to work on a replica with <code>lbr.replication=cache</code>, the replica should have one or more <code>p4 pull -u</code> threads configured (perhaps also using the <code>--batch=N</code> flag.)</p>

Command or Feature	Typical use case
Server names P4NAME p4d -In name	Helix Servers can be identified and configured by name. When you use p4 configure on your master server, you can specify different sets of configurables for each named server. Each named server, upon startup, refers to its own set of configurables, and ignores configurables set for other servers. <div style="background-color: #fff9e6; padding: 10px; border: 1px solid #ccc;"> <p>Important</p> <p>To avoid configuration problems, the value of <code>serverID</code> should always match the value of <code>P4NAME</code> if both are set. We recommend setting <code>serverID</code>, but support <code>P4NAME</code> for backward compatibility.</p> </div>
Service users p4d -u svcuser	A type of user intended for authentication of server-to-server communications. Service users have extremely limited access to the depot and do not consume Helix Server licenses. To make logs easier to read, create one service user on your master server for each replica or proxy in your network of Helix Servers .
Metadata access p4d -M readonly db.replication	Replica servers can be configured to automatically reject user commands that attempt to modify metadata (<code>db.*</code> files). In -M readonly mode, the Helix Core Server denies any command that attempts to write to server metadata. In this mode, a command such as p4 sync (which updates the server's have list) is rejected, but p4 sync -p (which populates a client workspace <i>without</i> updating the server's have list) is accepted.
Metadata filtering	Replica servers can be configured to filter in (or out) data on client workspaces and file revisions. You can use the -P serverId option with the p4d command to create a filtered checkpoint based on a serverId. You can use the -T tableexcludelist option with p4 pull to explicitly filter out updates to entire database tables. Using the <code>ClientDataFilter:</code> , <code>RevisionDataFilter:</code> , and <code>ArchiveDataFilter:</code> fields of the p4 server form can provide you with far more fine-grained control over what data is replicated. Use the -P serverid option with p4 pull , and specify the <code>Name:</code> of the server whose p4 server spec holds the desired set of filter patterns.

Command or Feature	Typical use case
Depot file access p4d -D readonly p4d -D shared p4d -D ondemand p4d -D cache p4d -D none <code>lbr.replication</code>	<p>Replica servers can be configured to automatically reject user commands that attempt to modify archived depot files (the “library”).</p> <ul style="list-style-type: none"> ■ In -D readonly mode, the Helix Core Server accepts commands that read depot files, but denies commands that write to them. In this mode, <code>p4 describe</code> can display the diffs associated with a changelist, but <code>p4 submit</code> is rejected. However, edge servers do have the capability to write some files, such as shelved files, to the depot. ■ In -D ondemand mode, or -D shared mode (the two are synonymous) the Helix Server accepts commands that read metadata, but does not transfer new files nor remove purged files from the master. (<code>p4 pull -u</code> and <code>p4 verify -t</code>, which would otherwise transfer archive files, are disabled.) If a file is not present in the archives, commands that reference that file will fail. This mode must be used when a replica directly shares the same physical archives as the target, whether by running on the same machine or via network sharing. This mode can also be used when an external archive synchronization technique, such as rsync is used for archives. ■ In -D cache mode, the Helix Core Server permits commands that reference file content, but does not automatically transfer new files. Files that are purged from the target are removed from the replica when the purge operation is replicated. If a file is not present in the archives, the replica will retrieve it from the target server. ■ In -D none mode, the Helix Core Server denies any command that accesses the versioned files that make up the depot. In this mode, a command such as <code>p4 describe changenum</code> is rejected because the diffs displayed with a changelist require access to the versioned files, but <code>p4 describe -s changenum</code> (which describes a changelist <i>without</i> referring to the depot files in order to generate a set of diffs) is accepted. <p>These options can also be set using <code>lbr.replication.*</code> configurables, described under “Configurables” in the P4 Command Reference.</p>

Command or Feature	Typical use case
Target server <code>P4TARGET</code>	<p>As with the Helix Proxy, you can use <code>P4TARGET</code> to specify the master server or another replica server to which a replica server points when retrieving its data.</p> <p>You can set <code>P4TARGET</code> explicitly, or you can use <code>p4 configure</code> to set a <code>P4TARGET</code> for each named replica server.</p> <p>A replica server with <code>P4TARGET</code> set must have both the <code>-M</code> and <code>-D</code> options, or their equivalent <code>db.replication</code> and <code>lbr.replication</code> configurables, correctly specified.</p>
Startup commands <code>startup.1</code>	Use the <code>startup.n</code> (where <code>n</code> is an integer) configurable to automatically spawn multiple <code>p4 pull</code> processes on startup.
State file <code>statefile</code>	<p>Replica servers track the most recent journal position in a small text file that holds a byte offset. When you stop either the master server or a replica server, the most recent journal position is recorded on the replica in the state file.</p> <p>Upon restart, the replica reads the state file and picks up where it left off; do not alter this file or its contents. (When the state file is written, a temporary file is used and moved into place, which should preserve the existing state file if something goes wrong when updating it. If the state file should be empty or missing, the replica server will refetch from the start of its last used journal position.)</p> <p>By default, the state file is named <code>state</code> and it resides in the replica server's root directory. You can specify a different file name by setting the <code>statefile</code> configurable.</p>
P4Broker	The Helix Broker can be used for load balancing, command redirection, and more. See "Helix Broker" on page 87 for details.

Warning

Replication requires uncompressed journals. Starting the master using the `p4d -jc -z` command breaks replication; use the `-Z` flag instead to prevent journals from being compressed.

The p4 pull command

The `p4 pull` command provides the most general solution for replication. Use `p4 pull` to configure a replica server that:

- replicates versioned files (the `,v` files that contain the deltas that are produced when new versions are submitted) unidirectionally from a master server.

- replicates server metadata (the information contained in the `db.*` files) unidirectionally from a master server.
- uses the `startup.n` configurable to automatically spawn as many `p4 pull` processes as required.

A common configuration for a warm standby server is one in which one (and only one) `p4 pull` process is spawned to replicate the master server's metadata, and multiple `p4 pull -u` processes are spawned to run in parallel, and continually update the replica's copy of the master server's versioned files.

- The `startup.n` configurables are processed sequentially. Processing stops at the first gap in the numerical sequence. Any commands after a gap are ignored.

Although you can run `p4 pull` from the command line for testing and debugging purposes, it's most useful when controlled by the `startup.n` configurables, and in conjunction with named servers, service users, and centrally-managed configurations.

The `--batch` option to the `p4 pull` specifies the number of files a pull thread should process in a single request. The default value of `1` is usually adequate. For high-latency configurations, a larger value might improve archive transfer speed for large numbers of small files. (Use of this option requires that both master and replica be at version 2015.2 or higher.)

Setting the `rp1.compress` configurable allows you to compress journal record data that is transmitted using `p4 pull`.

Note

If you are running a replica with monitoring enabled and you have not configured the monitor table to be disk-resident, you can run the following command to get more precise information about what pull threads are doing. (Remember to set `monitor.lsof`).

```
$ p4 monitor show -sB -la -L
```

Command output would look like this:

```
31701 B uservice-edge3 00:07:24 pull sleeping 1000 ms
      [server.locks/replica/49,d/pull(W)]
```

The possible status messages are:

For journal records	For pulling archives
scanned NNNN records	sleeping
applied NNNN records	running
rotating journal	

Identifying your server

Giving your server a unique ID permits most of the server configuration data to be stored in the Helix Core Server. This is an alternative to using startup options or environment variables. A unique server ID is essential for configuring replication because [p4 configure](#) settings are replicated from the master server to the replicas along with other metadata.

Configuring the following servers require the use of a server spec:

Type	Description
Commit server	central server in a distributed installation
Edge server	node in a distributed installation
Build server	replica that supports build farm integration
Standby server	read-only replica that uses p4 journalcopy
Forwarding standby	forwarding replica that uses p4 journalcopy

The [p4 serverid](#) command creates a small text file named `server.id` in the root directory of the server. The server executable, `p4d`, can also create this `server.id` file:

```
p4d -r $P4ROOT -xD
```

Tip

- To see the server id, use `p4d -xD` or the [p4 serverid](#) command.
- If the response is "Server does not yet have a server ID", set the server ID with `p4d -xD myServer`.
- To change an existing server ID, delete the `server.id` file, then set the server ID

You can use the [p4 server](#) command to:

- define a specification for each of the servers known to your installation
- create a unique server ID that can be passed to the [p4 serverid](#) command, and to define the services offered by any server that, upon startup, reads that server ID from a `server.id` file

For example, you can set your master server id to `myMaster` and the replica id to `myReplica`:

```
p4 -p svrA.company.com:11111 serverid myMaster
```

```
Server myMaster saved.
```

```
p4 -p svrB.company.com:22222 serverid myReplica
```

```
Server myReplica saved.
```

You can use [p4 configure](#) on the master instance to control settings on both the master and the replica because configuration settings are part of the replicated metadata of a Helix Server server.

For example, if you issue the following commands on the master server:

```
$ p4 -p svrA.company.com:11111 configure set myMaster#monitor=2
$ p4 -p svrA.company.com:11111 configure set myReplica#monitor=1
```

the two servers have different monitoring levels after the configuration data has been replicated. Therefore, if you run `p4 monitor show` against the master server, you see both active and idle processes because the `monitor` configurable is set to `2` for the master server. In contrast, if you run `p4 monitor show` against the replica, you see only active processes because `1` is the monitor setting.

A master and each replica is likely to have its own journal and checkpoint files. To ensure their prefixes are unique, use the `journalPrefix` configurable for each named server:

```
$ p4 -p svrA.company.com:11111 configure set
myMaster#journalPrefix=/p4/ckps/myMaster
For server 'myMaster', configuration variable 'journalPrefix' set
to '/p4/ckps/myMaster'
```

```
$ p4 -p svrA.company.com:11111 configure set
myReplica#journalPrefix=/p4/ckps/myReplica
For server 'myReplica', configuration variable 'journalPrefix'
set to '/p4/ckps/myReplica'
```

Service users

There are three types of Helix Server users: `standard` users, `operator` users, and `service` users. A `standard` user is a traditional user of Helix Server, an `operator` user is intended for human or automated system administrators, and a `service` user is used for server-to-server authentication, as part of the replication process.

Service users are useful for remote depots in single-server environments, but are required for multi-server and distributed environments.

Create a `service` user for each master, replica, or proxy server that you control. Doing so greatly simplifies the task of interpreting your server logs. Service users can also help you improve security, by requiring that your edge servers and other replicas have valid login tickets before they can communicate with the master or commit server. Service users do not consume Helix Server licenses.

Important

Read the "Service users" topic in *Helix Core Server Administrator Guide: Fundamentals*.

Tickets and timeouts for service users

A newly-created service user that is not a member of any groups is subject to the default ticket timeout of 12 hours. To avoid issues that arise when a service user's ticket ceases to be valid, create a group for your service users that features an extremely long timeout, or to **unlimited**. On the master server, issue the following command:

```
p4 group service_users
```

Add **service1** to the list of **Users:** in the group, and set the **Timeout:** and **PasswordTimeout:** values to a large value or to **unlimited**.

```
Group:          service_users
Timeout:        unlimited
PasswordTimeout: unlimited
Subgroups:
Owners:
Users:
    service1
```

Important

Service users *must* have a ticket created with the **p4 login** for replication to work.

Permissions for service users

On the master server, use **p4 protect** to grant the service user **super** permission. Service users are tightly restricted in the commands they can run, so granting them **super** permission is safe.

Server options to control metadata and depot access

When you start a replica that points to a master server with **P4TARGET**, you must specify both the **-M** (metadata access) and a **-D** (depot access) options, or set the configurables **db.replication** (access to metadata) and **lbr.replication** (access the depot's library of versioned files) to control which Helix Server commands are permitted or rejected by the replica server.

P4TARGET

Set **P4TARGET** to the the fully-qualified domain name or IP address of the master server from which a replica server is to retrieve its data. You can set **P4TARGET** explicitly, specify it on the **p4d** command line with the **-t protocol:host:port** option, or you can use **p4 configure** to set a **P4TARGET** for each named replica server. See the table below for the available **protocol** options.

If you specify a target, **p4d** examines its configuration for **startup.n** commands: if no valid **p4 pull** commands are found, **p4d** runs and waits for the user to manually start a **p4 pull** command. If you omit a target, **p4d** assumes the existence of an external metadata replication source such as **p4 replicate**. See "p4 pull vs. p4 replicate" on the next page for details.

Protocol	Behavior
<not set>	Use tcp4: behavior, but if the address is numeric and contains two or more colons, assume tcp6: . If the net.rfc3484 configurable is set, allow the OS to determine which transport is used.
tcp:	Use tcp4: behavior, but if the address is numeric and contains two or more colons, assume tcp6: . If the net.rfc3484 configurable is set, allow the OS to determine which transport is used.
tcp4:	Listen on/connect to an IPv4 address/port only.
tcp6:	Listen on/connect to an IPv6 address/port only.
tcp46:	Attempt to listen on/connect to an IPv4 address/port. If this fails, try IPv6.
tcp64:	Attempt to listen on/connect to an IPv6 address/port. If this fails, try IPv4.
ssl:	Use ssl4: behavior, but if the address is numeric and contains two or more colons, assume ssl6: . If the net.rfc3484 configurable is set, allow the OS to determine which transport is used.
ssl4:	Listen on/connect to an IPv4 address/port only, using SSL encryption.
ssl6:	Listen on/connect to an IPv6 address/port only, using SSL encryption.
ssl46:	Attempt to listen on/connect to an IPv4 address/port. If this fails, try IPv6. After connecting, require SSL encryption.
ssl64:	Attempt to listen on/connect to an IPv6 address/port. If this fails, try IPv4. After connecting, require SSL encryption.

P4TARGET can be the hosts' hostname or its IP address; both IPv4 and IPv6 addresses are supported. For the **listen** setting, you can use the ***** wildcard to refer to all IP addresses, but only when you are not using CIDR notation.

If you use the ***** wildcard with an IPv6 address, you must enclose the entire IPv6 address in square brackets. For example, **[2001:db8:1:2:*]** is equivalent to **[2001:db8:1:2::]/64**. Best practice is to use CIDR notation, surround IPv6 addresses with square brackets, and to avoid the ***** wildcard.

Server startup commands

You can configure Helix Server to automatically run commands at startup using the **p4 configure** as follows:

```
p4 configure set "servername#startup.n=command"
```

Where *n* represents the order in which the commands are executed: the command specified for `startup.1` runs first, then the command for `startup.2`, and so on. Key startup commands include `p4 pull` and `p4 journalcopy`.

p4 pull vs. p4 replicate

Helix Server also supports a more limited form of replication based on the `p4 replicate` command. This command does not replicate file content, but supports filtering of metadata on a per-table basis.

Enabling SSL support

To encrypt the connection between a replica server and its end users, the replica must have its own valid private key and certificate pair in the directory specified by its `P4SSLDIR` environment variable. Certificate and key generation and management for replica servers works the same as it does for the (master) server. See "Enabling SSL support" on page 89. The users' Helix Server applications must be configured to trust the fingerprint of the replica server.

To encrypt the connection between a replica server and its master, the replica must be configured so as to trust the fingerprint of the master server. That is, the user that runs the replica `p4d` (typically a service user) must create a `P4TRUST` file (using `p4 trust`) that recognizes the fingerprint of the *master* Helix Core Server.

The `P4TRUST` variable specifies the path to the SSL trust file. You must set this environment variable in the following cases:

- for a replica that needs to connect to an SSL-enabled master server, or
- for an edge server that needs to connect to an SSL-enabled commit server.

Replication and protections

To apply the IP address of a replica user's workstation against the protections table, prepend the string `proxy-` to the workstation's IP address.

Important

Before you prepend the string `proxy-` to the workstation's IP address, make sure that a broker or proxy is in place.

For instance, consider an organization with a remote development site with workstations on a subnet of `192.168.10.0/24`. The organization also has a central office where local development takes place; the central office exists on the `10.0.0.0/8` subnet. A Perforce service resides in the `10.0.0.0/8` subnet, and a replica resides in the `192.168.10.0/24` subnet. Users at the remote site belong to the group `remotedev`, and occasionally visit the central office. Each subnet also has a corresponding set of IPv6 addresses.

To ensure that members of the `remotedev` group use the replica while working at the remote site, but do not use the replica when visiting the local site, add the following lines to your protections table:

```
list    group    remotedev    192.168.10.0/24    -//...
list    group    remotedev    [2001:db8:16:81::]/48    -//...
write   group    remotedev    proxy-192.168.10.0/24    //...
write   group    remotedev    proxy-[2001:db8:16:81::]/48    //...
list    group    remotedev    proxy-10.0.0.0/8    -//...
list    group    remotedev    proxy-[2001:db8:1008::]/32    -//...
write   group    remotedev    10.0.0.0/8    //...
write   group    remotedev    proxy-[2001:db8:1008::]/32    //...
```

The first line denies `list` access to all users in the `remotedev` group if they attempt to access Helix Server without using the replica from their workstations in the `192.168.10.0/24` subnet. The second line denies access in identical fashion when access is attempted from the IPV6 `[2001:db8:16:81::]/48` subnet.

The third line grants `write` access to all users in the `remotedev` group if they are using the replica and are working from the `192.168.10.0/24` subnet. Users of workstations at the remote site must use the replica. (The replica itself does not have to be in this subnet, for example, it could be at `192.168.20.0`.) The fourth line grants access in identical fashion when access is attempted from the IPV6 `[2001:db8:16:81::]/48` subnet.

Similarly, the fifth and sixth lines deny `list` access to `remotedev` users when they attempt to use the replica from workstations on the central office's subnets (`10.0.0.0/8` and `[2001:db8:1008::]/32`). The seventh and eighth lines grant write access to `remotedev` users who access the Helix Server directly from workstations on the central office's subnets. When visiting the local site, users from the `remotedev` group must access the Helix Server directly.

When the Perforce service evaluates protections table entries, the `dm.proxy.protects` configurable is also evaluated:

- `dm.proxy.protects` defaults to `1`, which causes the `proxy-` prefix to be prepended to all client host addresses that connect via an intermediary (proxy, broker, replica, or edge server), indicating that the connection is not direct.
- Setting `dm.proxy.protects` to `0` removes the `proxy-` prefix, which allows you to write a single set of protection entries that apply both to directly-connected clients and clients that connect via an intermediary. This is more convenient but might be less secure insofar as a connection is made using an intermediary. If you use this setting, all intermediaries must be at release 2012.1 or higher.

How replica types handle requests

Replica servers differ in how they respond to user commands:

Replica type	Global update commands	Read-only commands	Work-in-progress commands
Standby, replica	Reject	Local	Reject
Forwarding standby, forwarding replica	Forward	Local	Forward
Build server (for client creation and local sync)	p4 client	Local	p4 sync
Edge server	Forward	Local	Local
Standard server, commit server	Local	Local	Local

User requests fall into three categories, depending on the command and command options:

Global update	Read-only	Work-in-progress
p4 branch	p4 branches	p4 add
p4 change	p4 changes	p4 edit
p4 configure set	p4 configure show	p4 delete
p4 client	p4 client -o	p4 diff
	p4 clients	p4 integrate
p4 counter	p4 counters	p4 reconcile
p4 depot	p4 depots	p4 resolve
	p4 dirs	p4 revert
	p4 filelog	p4 shelve
	p4 files	p4 submit
	p4 fstat	p4 sync
	p4 fixes	p4 unshelve
p4 group	p4 groups	
	p4 interchanges	
p4 job	p4 jobs	
p4 label	p4 labels	
	p4 opened	
p4 protect		
p4 server	p4 servers	
p4 stream	p4 streams	
p4 triggers		
p4 typemap		
	p4 sizes	
p4 user	p4 user -o	
	p4 users	
	p4 where	
	p4 workspaces	

Tip

For a more detailed summary of replica server types, see the Support Knowledgebase article "[Replica Types and Use Cases](#)".

Configuring a read-only replica

To support warm standby servers, a replica server requires an up-to-date copy of both the master server's metadata and its versioned files.

Tip

To help the standby server stay as current as possible with the master server, consider setting the `rpl.journalcopy.location` configurable. The value of `1` could keep the standby server's journalcopy more current with the master server's journal by writing the journalcopy to a faster device than the device in the `journalPrefix` configurable defined for the standby server.

Note

Replication is asynchronous, and a replicated server is not recommended as the sole means of backup or disaster recovery. **We recommend that you maintain a separate set of database checkpoints and depot backups.**

In addition, see the [Failover](#) topic in *Helix Core Server Administrator Guide: Fundamentals*.

Disaster recovery and failover strategies can be complex and site-specific, in which case [Perforce Consultants](#) are available to assist organizations in planning and deployment.

The following extended example configures a replica as a warm standby server for an existing Helix Core Server with some data in it. For this example, assume that:

- Your master server is named `Master` and is running on a host called `master`, using port `11111`, and its server root directory is `/p4/master`.
- Your replica server will be named `Replica1` and will be configured to run on a host machine named `replica`, using port `22222`, and its root directory will be `/p4/replica`.
- The service user name is `service`.

Note

You cannot define `P4NAME` using the `p4 configure` command, because a server must know its own name to use values set by `p4 configure`.

You cannot define `P4ROOT` using the `p4 configure` command, to avoid the risk of specifying an incorrect server root.

Important

To avoid configuration problems, the value of `serverID` should always match the value of `P4NAME` if both are set. We recommend setting `serverID`, but support `P4NAME` for backward compatibility.

Master server setup

To define the behavior of the replica, you enter configuration information into the master server's `db.config` file using the `p4 configure set` command. Configure the master server first; its settings will be replicated to the replica later.

To configure the master, log in to Helix Server as a superuser and perform the following steps:

1. To set the server named `Replica1` to use `master:11111` as the master server to pull metadata and versioned files, issue the command:

```
$ p4 -p master:11111 configure set
Replica1#P4TARGET=master:11111
```

Helix Server displays the following response:

```
For server Replica1, configuration variable 'P4TARGET' set to
'master:11111'
```

Note

To avoid confusion when working with multiple servers that appear identical in many ways, use the `-u` option to specify the superuser account and `-p` to explicitly specify the master Helix Server's host and port.

These options have been omitted from this example for simplicity. In a production environment, specify the host and port on the command line.

2. Set the `Replica1` server to save the replica server's log file using a specified file name. Keeping the log names unique prevents problems when collecting data for debugging or performance tracking purposes.

```
$ p4 configure set Replica1#P4LOG=replica1Log.txt
```

3. Set the `Replica1 server` configurable to `1`, which is equivalent to specifying the `-vserver=1` server startup option:

```
$ p4 configure set Replica1#server=1
```

4. To enable process monitoring, set `Replica1's monitor` configurable to `1`:

```
$ p4 configure set Replica1#monitor=1
```

- To handle the `Replica1` replication process, configure the following three `startup.N` commands. (When passing multiple items separated by spaces, you must wrap the entire set value in double quotes.)

The first startup process sets `p4 pull` to poll once every second for journal data only:

```
$ p4 configure set "Replica1#startup.1=pull -i 1"
```

The next two settings configure the server to spawn two `p4 pull` threads at startup, each of which polls once per second for archive data transfers.

```
$ p4 configure set "Replica1#startup.2=pull -u -i 1"
```

```
$ p4 configure set "Replica1#startup.3=pull -u -i 1"
```

Each `p4 pull -u` command creates a separate thread for replicating archive data. Heavily-loaded servers might require more threads if archive data transfer begins to lag behind the replication of metadata. To determine if you need more `p4 pull -u` processes, read the contents of the `rdb.lbr` table, which records the archive data transferred from the master Helix Server to the replica.

To display the contents of this table when a replica is running, run:

```
$ p4 -p replica:22222 pull -l
```

Likewise, if you only need to know how many file transfers are active or pending, use `p4 -p replica:22222 pull -l -s`.

If `p4 pull -l -s` indicates a large number of pending transfers, consider adding more `p4 pull -u startup.n` commands to address the problem.

If a specific file transfer is failing repeatedly (perhaps due to unrecoverable errors on the master), you can cancel the pending transfer with `p4 pull -d -f file -r rev`, where `file` and `rev` refer to the file and revision number.

- Set the `db.replication` (metadata access) and `lbr.replication` (depot file access) configurables to `readonly`:

```
$ p4 configure set Replica1#db.replication=readonly
```

```
$ p4 configure set Replica1#lbr.replication=readonly
```

Because this replica server is intended as a warm standby (failover) server, both the master server's metadata and its library of versioned depot files are being replicated. When the replica is running, users of the replica will be able to run commands that access both metadata and the server's library of depot files.

7. Create the service user:

```
$ p4 user -f service
```

The user specification for the `service` user opens in your default editor. Add the following line to the user specification:

```
Type: service
```

Save the user specification and exit your default editor.

By default, the service user is granted the same 12-hour login timeout as standard users. To prevent the service user's ticket from timing out, create a group with a long timeout on the master server. In this example, the `Timeout:` field is set to two billion seconds, approximately 63 years:

```
$ p4 group service_group
```

```
Users: service
```

```
Timeout: 2000000000
```

For more details, see "[Tickets and timeouts for service users](#)" in *Helix Core Server Administrator Guide: Fundamentals*.

8. Set the service user protections to `super` in your protections table. (See "[Permissions for service users](#)" on page 34.) It is good practice to set the security level of all your Helix Servers to at least 1 (preferably to 3, so as to require a strong password for the service user, and ideally to 4, to ensure that *only* authenticated service users may attempt to perform replica or remote depot transactions.)

```
$ p4 configure set security=4
```

```
$ p4 passwd
```

9. Set the `Replica1` configurable for the `serviceUser` to `service`.

```
$ p4 configure set Replica1#serviceUser=service
```

This step configures the replica server to authenticate itself to the master server as the `service` user; this is equivalent to starting `p4d` with the `-u service` option.

10. If the user running the replica server does not have a home directory, or if the directory where the default `.p4tickets` file is typically stored is not writable by the replica's Helix Server process, set the replica `P4TICKETS` value to point to a writable ticket file in the replica's Helix Server root directory:

```
$ p4 configure set
"Replica1#P4TICKETS=/p4/replica/.p4tickets"
```

Next step

["Creating the replica" below](#)

Creating the replica

To configure and start a replica server, perform the following steps:

1. Boot-strap the replica server by checkpointing the master server, and restoring that checkpoint to the replica:

```
$ p4 admin checkpoint
```

(For a new setup, we can assume the checkpoint file is named `checkpoint.1`)

2. Move the checkpoint to the replica server's `P4ROOT` directory and replay the checkpoint:

```
$ p4d -r /p4/replica -jr $P4ROOT/checkpoint.1
```

3. Copy the versioned files from the master server to the replica.

Versioned files include both text (in RCS format, ending with `,v`) and binary files (directories of individual binary files, each directory ending with `,d`). Ensure that you copy the text files in a manner that correctly translates line endings for the replica host's filesystem.

If your depots are specified using absolute paths on the master, use the same paths on the replica. (Or use relative paths in the `Map:` field for each depot, so that versioned files are stored relative to the server's root.)

4. To create a valid ticket file, use `p4 login` to connect to the master server and obtain a ticket on behalf of the replica server's service user. On the machine that will host the replica server, run:

```
$ p4 -u service -p master:11111 login
```

Then move the ticket to the location that holds the `P4TICKETS` file for the replica server's service user.

At this point, your replica server is configured to contact the master server and start replication. Specifically:

- A service user (`service`) in a group (`service_group`) with a long ticket timeout
- A valid ticket for the replica server's service user (from `p4 login`)

- A replicated copy of the master server's `db.config`, holding the following preconfigured settings applicable to any server with a `P4NAME` of `Replica1`, specifically:
 - A specified service user (named `service`), which is equivalent to specifying `-u service` on the command line
 - A target server of `master:11111`, which is equivalent to specifying `-t master:11111` on the command line
 - Both `db.replication` and `lbr.replication` set to `readonly`, which is equivalent to specifying `-M readonly -D readonly` on the command line
 - A series of `p4 pull` commands configured to run when the master server starts

Important

To avoid configuration problems, the value of `serverID` should always match the value of `P4NAME` if both are set. We recommend setting `serverID`, but support `P4NAME` for backward compatibility.

Next step

"Starting the replica" below

Starting the replica

To name your server `Replica1`, set `P4NAME` or specify the `-In` option and start the replica as follows:

```
$ p4d -r /p4/replica -In Replica1 -p replica:22222 -d
```

Important

To avoid configuration problems, the value of `serverID` should always match the value of `P4NAME` if both are set. We recommend setting `serverID`, but support `P4NAME` for backward compatibility.

When the replica starts, all of the master server's configuration information is read from the replica's copy of the `db.config` table (which you copied earlier). The replica then spawns three `p4 pull` threads: one to poll the master server for metadata, and two to poll the master server for versioned files.

Note

The `p4 info` command displays information about replicas and service fields for untagged output as well as tagged output.

Next step

"Testing the replica" on the next page

Testing the replica

Testing p4 pull

To confirm that the `p4 pull` commands (specified in the `Replica1 startup.N` configurations) are running, issue the following command:

```
$ p4 -u super -p replica:22222 monitor show -a
18835 R service00:04:46 pull -i 1
18836 R service00:04:46 pull -u -i 1
18837 R service00:04:46 pull -u -i 1
18926 R super 00:00:00 monitor show -a
```

If you need to stop replication for any reason, use the `p4 monitor terminate` command:

```
$ p4 -u super -p replica:22222 monitor terminate 18837 process
'18837' marked for termination
```

To restart replication, either restart the Helix Server process, or manually restart the replication command:

```
$ p4 -u super -p replica:22222 pull -u -i 1
```

Note

If the `p4 pull` and/or `p4 pull -u` processes are terminated, read-only commands continue to work for replica users as long as the replica server's `p4d` is running.

Testing file replication

Create a new file under your workspace view:

```
$ echo "hello world" > myfile
```

Mark the file for add:

```
$ p4 -p master:11111 add myfile
```

And submit the file:

```
$ p4 -p master:11111 submit -d "testing replication"
```

Wait a few seconds for the pull commands on the replica to run, then check the replica for the replicated file:

```
$ p4 -p replica:22222 print //depot/myfile
//depot/myfile#1 - add change 1 (text)
hello world
```

If a file transfer is interrupted for any reason, and a versioned file is not present when requested by a user, the replica server silently retrieves the file from the master.

Note

Replica servers in `-M readonly -D readonly` mode retrieve versioned files from master servers even if started without a `p4 pull -u` command to replicate versioned files to the replica. Such servers act as "on-demand" replicas, as do servers running in `-M readonly -D ondemand` mode or with their `lbr.replication` configurable set to `ondemand`.

Creating an on-demand replica of this sort can affect server performance or resource consumption. For example, if a user enters a command such as `p4 print //...`, which reads every file in the depot.

Verifying the replica

When you copied the versioned files from the master server to the replica server, you relied on the operating system to transfer the files. To determine whether data was corrupted in the process, run `p4 verify` on the replica server:

```
$ p4 verify //...
```

Any errors that are present on the replica but not on the master indicate corruption of the data in transit or while being written to disk during the original copy operation.

Tip

Run `p4 verify` on a regular basis because any server's storage is vulnerable to corruption.

Next step

"Using the replica" below

Using the replica

You can perform all normal operations against your master server (`p4 -p master:11111 command`). To reduce the load on the master server, direct reporting (read-only) commands to the replica (`p4 -p replica:22222 command`). Because the replica is running in `-M readonly -D readonly` mode, commands that read both metadata and depot file contents are available, and reporting commands (such as `p4 annotate`, `p4 changes`, `p4 filelog`, `p4 diff2`, `p4 jobs`, and others) work normally. However, commands that update the server's metadata or depot files are blocked.

Commands that update metadata

Some scenarios are relatively straightforward: consider a command such as `p4 sync`. A plain `p4 sync` fails, because whenever you sync your workspace, the Helix Core Server must update its metadata (the "have" list, which is stored in the `db.have` table). Instead, use `p4 sync -p` to populate a workspace without updating the have list:

```
$ p4 -p replica:22222 sync -p //depot/project/...@1234
```

This operation succeeds because it does not update the server's metadata.

Some commands affect metadata in more subtle ways. For example, many Helix Server commands update the last-update time that is associated with a specification (for example, a user or client specification). Attempting to use such commands on replica servers produces errors unless you use the `-o` option. For example, `p4 client` (which updates the `Update:` and `Access:` fields of the client specification) fails:

```
$ p4 -p replica:22222 client replica_client
```

```
Replica does not support this command.
```

However, `p4 client -o` works:

```
$ p4 -p replica:22222 client -o replica_client
```

```
(client spec is output to STDOUT)
```

If a command is blocked due to an implicit attempt to write to the server's metadata, consider workarounds such as those described above. (Some commands, like `p4 submit`, always fail, because they attempt to write to the replica server's depot files; these commands are blocked by the `-D readonly` option.)

Using the Helix Broker to redirect commands

You can use the Helix Broker with a replica server to redirect read-only commands to replica servers. This approach enables all your users to connect to the same `protocol:host:port` setting (the broker). In this configuration, the broker is configured to transparently redirect key commands to whichever Helix Core Server is appropriate to the task at hand.

For an example of such a configuration, see the Support Knowledge base article, "[Using P4Broker to redirect read-only commands](#)".

See also the chapter on "[Helix Broker](#)" on page 87.

Next step

["Upgrading replica servers" on the facing page](#)

Upgrading replica servers

Upgrade replicas before upgrading the master

We recommend that you first upgrade any server instance replicating from a master server. If replicas are chained together, start at the replica that is furthest downstream from the master, and work upstream towards the master server. Keep downstream replicas stopped until the server immediately upstream is upgraded. Minimize the time between the upgrades.

Note

There has been a significant change in release 2013.3 that affects how metadata is stored in `db.*` files; despite this change, the database schema and the format of the checkpoint and the journal files between 2013.2 and 2013.3, remains unchanged.

Consequently, in this one case (of upgrades between 2013.2 and 2013.3), it is sufficient to stop the replica until the master is upgraded, but the replica (and any replicas downstream of it) must be upgraded to *at least* 2013.2 before a 2013.3 master is restarted.

When upgrading between 2013.2 (or lower) and 2013.3 (or higher):

- before shutting down the replica and commencing the upgrade, wait for all archive transfers to end
- before restarting the replica, you must manually delete the `rdb.lbr` file in the replica server's root

Steps to upgrade a replica server in a p4 pull environment

Note

If you are changing the hostname or IP of the master server, additional steps are required.

The following process is the same for all replica types, whether you are working with a read-only replica, a forwarding replica, a build farm server, or commit-edge.

On the replica

1. Stop the replica server with `p4 admin stop`.
2. Take a checkpoint of the replica server: `p4d -r /usr/replica/root -J journal -jd checkpoint`
3. Replace the replica server's `p4d` executable.
4. Upgrade the replica database: `p4d -r /usr/replica/root -J journal -xu`
5. For each of your replica servers, repeat steps 1 - 4.

On the master

1. Stop the master server:

```
p4 admin stop
```

2. Take a checkpoint of the master server and back up its versioned files:

```
p4d -r /usr/master/root -J journal -jc prefix
```

where **prefix** is the journal prefix that the production environment uses.

Note

The only way to recover from failures that might occur during the upgrade process is to restore from this checkpoint.

3. Replace the master server's **p4d** executable.

4. Upgrade the master database:

```
p4d -r /usr/master/root -J journal -xu
```

5. Start the upgraded master server:

```
p4d -p 1666 -r /usr/master/root -J journal -d
```

On each of the upgraded replica servers

Start that server:

```
p4d -M readonly -D readonly -In Replica2 -p 6661 -r /usr/replica/root -J journal -d
```

Configuring a forwarding replica

A forwarding replica offers a blend of the functionality of the Helix Proxy with the improved performance of a replica.

If you are auditing server activity, each of your forwarding replica servers must have its own **P4AUDIT** log configured.

Note

For upgrading, see "Upgrading replica servers" on the previous page.

Configuring the master server

The following example assumes an environment with a regular server named **master**, and a forwarding replica server named **fwd-replica** on a host named **forward**.

Important

Prerequisite:

Start by configuring a read-only replica. For details, see ["Configuring a read-only replica" on page 40](#). (Instead of **Replica1**, use the name **fwd-replica**.)

1. On the master server, configure the forwarding replica as follows:

```
$ p4 server fwd-1667
```

The following form is displayed:

```
ServerID:      fwd-1667
Name:         fwd-replica
Type:        server
Services:    forwarding-replica
Address:     tcp:forward:1667
Description:
             Forwarding replica pointing to master:1666
```

Next step

["Configuring the forwarding replica" below](#)

Configuring the forwarding replica

1. On the replica machine, assign the replica server a serverID:

```
$ p4 serverid fwd-1667
```

When the replica server with the **serverID:** of **fwd-1667** (which was previously assigned the **Name:** of **fwd-replica**) pulls its configuration from the master server, it will behave as a forwarding replica.

2. On the replica machine, restart the replica server:

```
$ p4 admin restart
```

Configuring a build farm server

Continuous integration and other similar development processes can impose a significant workload on your Helix Server infrastructure. Automated build processes frequently access the Helix Server to monitor recent changes and retrieve updated source files; their client workspace definitions and associated have lists also occupy storage and memory on the server. With a build farm server, you can offload the workload of the automated build processes to a separate machine, and ensure that your main Helix Server's resources are available to your users for their normal day-to-day tasks.

Note

Build farm servers were implemented in Helix Server release 2012.1. With the implementation of edge servers in 2013.2, we now recommend that you use an edge server instead of a build farm server. As discussed in "[Commit-edge](#)" on page 64, edge servers offer all the functionality of build farm servers and yet offload more work from the main server and improve performance, with the additional flexibility of being able to run write commands as part of the build process.

A Helix Core Server intended for use as a build farm must, by definition:

- Permit the creation and configuration of client workspaces
- Permit those workspaces to be synced

One issue with implementing a build farm rather than a read-only replica is that under Helix Server, both of those operations involve writes to metadata:

- in order to use a client workspace in a build environment, the workspace must contain some information (even if nothing more than the client workspace root) specific to the build environment
- in order for a build tool to efficiently sync a client workspace, a build server must be able to keep some record of which files have already been synced.

To address these issues, build farm replicas host their own local copies of certain metadata. In addition to the Helix Server commands supported in a read-only replica environment, build farm replicas support the `p4 client` and `p4 sync` commands when applied to workspaces that are bound to that replica.

If you are auditing server activity, each of your build farm replica servers must have its own `P4AUDIT` log configured.

Note

For upgrading, see "[Upgrading replica servers](#)" on page 49.

Configuring the master server

The following example assumes an environment with a regular server named `master`, and a build farm replica server named `buildfarm1` on a host named `builder`.

Important

Prerequisite:

Start by configuring a read-only replica. For details, see ["Configuring a read-only replica" on page 40](#). (Instead of `Replica1`, use the name `buildfarm1`.)

1. On the master server, configure the master server as follows:

```
$ p4 server master-1666
```

The following form is displayed:

```
ServerID:      master-1666
Name:         master-1666
Type:        server
Services:    standard
Address:     tcp:master:1666
Description:
             Master server - regular development work
```

2. Create the master server's `server.id` file. On the master server, run the following command:

```
$ p4 -p master:1666 serverid master-1666
```

Important

To avoid configuration problems, the value of `serverID` should always match the value of `P4NAME` if both are set. We recommend setting `serverID`, but support `P4NAME` for backward compatibility.

3. Restart the master server.

On startup, the master server reads its server ID of `master-1666` from its `server.id` file. It takes on the `P4NAME` of `master` and uses the configurables that apply to a `P4NAME` setting of `master`.

Next step

["Configuring the build farm replica" on the next page](#)

Configuring the build farm replica

1. On the master server, configure the build farm replica server as follows:

```
$ p4 server builder-1667
```

The following form is displayed:

```
ServerID:      builder-1667
Name:         builder-1667
Type:        server
Services:     build-server
Address:      tcp:builder:1667
Description:
              Build farm - bind workspaces to builder-1667
              and use a port of tcp:builder:1667
```

2. Create the build farm replica server's `server.id` file. On the *replica* server (not the master server), run the following command

```
$ p4 -p builder:1667 serverid builder-1667
```

3. Restart the replica server.

On startup, the replica build farm server reads its server ID of `builder-1667` from its `server.id` file.

Because the server registry is automatically replicated from the master server to all replica servers, the restarted build farm server takes on the `P4NAME` of `buildfarm1` and uses the configurables that apply to a `P4NAME` setting of `buildfarm1`.

Important

To avoid configuration problems, the value of `serverID` should always match the value of `P4NAME` if both are set. We recommend setting `serverID`, but support `P4NAME` for backward compatibility.

In this example, the build farm server also acknowledges the `build-server` setting in the `Services:` field of its `p4 server` form.

Next step

"Binding workspaces to the build farm replica" below

Binding workspaces to the build farm replica

At this point, there should be two servers in operation:

- a master server named `master`, with a server ID of `master-1666`
- a `build-server` replica named `buildfarm1`, with a server ID of `builder-1667`

1. Bind client workspaces to the build farm server.

Because this server is configured to offer the `build-server` service, it maintains its own local copy of the list of client workspaces (`db.domain` and `db.view.rp`) and their respective have lists (`db.have.rp`).

On the replica server, create a client workspace with `p4 client`:

```
$ p4 -c build0001 -p builder:1667 client build0001
```

When creating a new workspace on the build farm replica, you must ensure that your current client workspace has a `ServerID` that matches the `ServerID` required by `builder:1667`. Because workspace `build0001` does not yet exist, you must manually specify `build0001` as the current client workspace with the `-c clientname` option and simultaneously supply `build0001` as the argument to the `p4 client` command. See the Support Knowledgebase article on "[Build Farm Client Management](#)".

When the `p4 client` form appears, set the `ServerID:` field to `builder-1667`. If the `ServerID` is not set manually, it will be set automatically when the form is saved.

2. Sync the bound workspace.

Because the client workspace `build0001` is bound to `builder-1667`, users on the master server are unaffected. However, users on the build farm server are not only able to edit its specification, they are able to sync it:

```
$ export P4PORT=builder:1667
$ export P4CLIENT=build0001
$ p4 sync
```

The replica's have list is updated, and does not propagate back to the master. Users of the master server are unaffected.

In a real-world scenario:

- your organization's build engineers would re-configure your site's build system to use the new server by resetting their `P4PORT` to point directly at the build farm server. Even in an environment in which continuous integration and automated build tools create a client workspace (and sync it) for every change submitted to the master server, performance on the master would be unaffected.
- performance on the master is likely to improve for all users because of the reduction of read and write operations on the master server's database.

If there are database tables that you know your build farm replica does not require, consider using the `-F` and `-T` filter options to `p4 pull`. Also consider specifying the `ArchiveDataFilter:`, `RevisionDataFilter:` and `ClientDataFilter:` fields of the replica's `p4 server` form.

If your automation load exceeds the capacity of a single machine, you can configure any number of additional build farm servers.

Configuring a replica with shared archives

Normally, a replica service retrieves its metadata and file archives on the user-defined pull interval, for example `p4 pull -i 1`. When the `lbr.replication` configurable is set to `ondemand` or `shared` (the two are synonymous), metadata is retrieved on the pull interval and archive files are retrieved only when requested by a client. New files are not automatically transferred, nor are purged files removed.

When a replica server is configured to directly share the same physical archive files as the master server, whether the replica and master are running on the same machine or via network shared storage, the replica accesses the archives directly without requiring the master to send the archives files to the replica. This can form part of a High Availability configuration.

Note

If shared storage is over a network, network latency affects performance.

Warning

When archive files are directly shared between a replica and master server, the replica *must* have `lbr.replication` set to `ondemand` or `shared`, or archive corruption may occur.

To configure a replica to share archive files with a master, perform the following steps:

1. Ensure that the clocks for the master and replica servers are synchronized.

Nothing needs to be done if the master and replica servers are hosted on the same operating system.

Synchronizing clocks is a system administration task that typically involves using a Network Time Protocol client to synchronize an operating system's clock with a time server on the Internet, or a time server you maintain for your own network.

See <http://support.ntp.org/bin/view/Support/InstallingNTP> for details.

2. If you have not already done so, configure the replica server as a forwarding replica.

See "Configuring a read-only replica" on page 40.

3. Set `lbr.replication`.

For example: `p4 configure set REP13-1#lbr.replication=ondemand`

4. Restart the replica, specifying the share archive location for the replica's root.

Once these steps have been completed, the following conditions are in effect:

- archive file content is only retrieved when requested, and those requests are made against the shared archives.
- no entries are written to the `rdb.lbr` librarian file during replication.

- commands that would schedule the transfer of file content, such as `p4 pull -u` and `p4 verify -t` are rejected:

```
$ p4 pull -u
```

This command is not used with an ondemand replica server.

```
$ p4 verify -t //depot/...
```

This command is not used with an ondemand replica server.

- if startup configurables, such as `startup.N=pull -u`, are defined, the replica server attempts to run such commands. Since the attempt to retrieve archive content is rejected, the replica's server log will contain the corresponding error:

```
Perforce server error:
```

```
2014/01/23 13:02:31 pid 6952 service-od@211131 background
```

```
'pull -u -i 10'
```

```
This command is not used with an ondemand replica server.
```

Note

For upgrading, see ["Upgrading replica servers" on page 49](#).

Filtering metadata during replication

As part of an HA/DR solution, you typically want to ensure that all the metadata and all the versioned files are replicated. In most other use cases, particularly build farms and/or forwarding replicas, this leads to a great deal of redundant data being transferred.

It is often advantageous to configure your replica servers to filter in (or out) data on client workspaces and file revisions. For example, developers working on one project at a remote site do not typically need to know the state of every client workspace at other sites where other projects are being developed, and build farms don't require access to the endless stream of changes to office documents and spreadsheets associated with a typical large enterprise.

The simplest way to filter metadata is by using the `-T tableexcludelist` option with `p4 pull` command. If you know, for example, that a build farm has no need to refer to *any* of your users' `have` lists or the state of their client workspaces, you can filter out `db.have` and `db.working` entirely with `p4 pull -T db.have,db.working`.

Excluding entire database tables is a coarse-grained method of managing the amount of data passed between servers, requires some knowledge of which tables are most likely to be referred to during Helix Server command operations, and offers no means of control over which versioned files are replicated.

You can gain much more fine-grained control over what data is replicated by using the `ClientDataFilter:`, `RevisionDataFilter:`, and `ArchiveDataFilter:` fields of the `p4 server` form. These options enable you to replicate (or exclude from replication) those portions of your server's metadata and versioned files that are of interest at the replica site.

Example Filtering out client workspace data and files

If workspaces for users in each of three sites are named with `site[123]-ws-username`, a replica intended to act as partial backup for users at `site1` could be configured as follows:

```
ServerID:      site1-1668
Name:         site1-1668
Type:         server
Services:     replica
Address:      tcp:site1bak:1668
Description:
    Replicate all client workspace data, except the states of
    workspaces of users at sites 2 and 3.
    Automatically replicate .c files in anticipation of user
    requests. Do not replicate .mp4 video files, which tend
    to be large and impose high bandwidth costs.
ClientDataFilter:
    -//site2-ws-*
    -//site3-ws-*
RevisionDataFilter:
ArchiveDataFilter:
    //....c
    -//....mp4
```

When you start the replica, your `p4 pull` metadata thread might resemble the following:

```
$ p4 configure set "site1-1668#startup.1=pull -i 30"
```

In this configuration, only those portions of `db.have` that are associated with `site1` are replicated. All metadata concerning workspaces associated with `site2` and `site3` is ignored.

All file-related metadata is replicated. All files in the depot are replicated, except for those ending in `.mp4`. Files ending in `.c` are transferred automatically to the replica when submitted.

To further illustrate the concept, consider a build farm replica scenario. The ongoing work of the organization (such as code, business documents, or videos) can be stored anywhere in the depot, but this build farm is dedicated to building releasable products, and has no need to have the rest of the organization's output at its immediate disposal:

Example Replicating metadata and file contents for a subset of a depot

Releasable code is placed into `//depot/releases/...` and automated builds are based on these changes. Changes to other portions of the depot, as well as the states of individual workers' client workspaces, are filtered out.

```

ServerID:      builder-1669
Name:         builder-1669
Type:         server
Services:     build-server
Address:      tcp:buil:1669
Description:
    Exclude all client workspace data
    Replicate only revisions in release branches
ClientDataFilter:
    -//...
RevisionDataFilter:
    -//...
    //depot/releases/...
ArchiveDataFilter:
    -//...
    //depot/releases/...

```

To seed the replica, you can use a command like the following to create a filtered checkpoint:

```
$ p4d -r /p4/master -P builder-1669 -jd myCheckpoint
```

The filters specified for `builder-1669` are used in creating the checkpoint. You can then continue to update the replica using the `p4 pull` command.

When you start the replica, your `p4 pull` metadata thread might resemble the following:

```
$ p4 configure set "builder-1669#startup.1=pull -i 30"
```

The `p4 pull` thread that pulls metadata for replication filters out all client workspace data (including the `have` lists) of all users.

The `p4 pull -u` thread(s) ignore all changes on the master except those that affect revisions in the `//depot/releases/...` branch, which are the only ones of interest to a build farm. The only metadata that is available is that which concerns released code. All released code is automatically transferred to the build farm before any requests are made, so that when the build farm performs a `p4 sync`, the sync is performed locally.

Verifying replica integrity

Tools to ensure data integrity in multi-server installations are accessed through the `p4 journaldbchecksums` command, and their behavior is controlled by three configurables: `rpl.checksum.auto`, `rpl.checksum.change`, and `rpl.checksum.table`.

When you run `p4 journaldbchecksums` against a specific database table (or the set of tables associated with one of the levels predefined by the `rpl.checksum.auto` configurable), the upstream server writes a journal note containing table checksum information. Downstream replicas, upon receiving this journal note, verify these checksums and record their results in the structured log for integrity-related events.

These checks are also performed whenever the journal is rotated. In addition, newly defined triggers allow you to take some custom action when journals are rotated. See "[Triggering on journal rotation](#)" in *Helix Core Server Administrator Guide: Fundamentals*.

Administrators who have one or more replica servers deployed should enable structured logging for integrity events, set the `rpl.checksum.*` configurables for their replica servers, and regularly monitor the logs for integrity events.

Configuration

Structured server logging must be enabled on every server, with at least one log recording events of type `integrity`, for example:

```
$ p4 configure set serverlog.file.8=integrity.csv
```

After you have enabled structured server logging, set the following configurables to the desired levels of integrity checking:

- `rpl.checksum.auto`
- `rpl.checksum.change`
- `rpl.checksum.table`

Best practice for most sites is a balance between performance and log size:

`p4 configure set rpl.checksum.auto=1` (or `2` for additional verification that is unlikely to vary between an upstream server and its replicas.)

`p4 configure set rpl.checksum.change=2` (this setting checks the integrity of every changelist, but only writes to the log if there is an error.)

`p4 configure set rpl.checksum.table=1` (this setting instructs replicas to verify table integrity on scan or unload operations, but only writes to the log if there is an error.)

Valid settings for `rpl.checksum.auto` are:

<code>rpl.checksum.auto</code>	Database tables checked with every journal rotation
<code>0</code>	No checksums are performed.

<code>rpl.checksum.auto</code>	Database tables checked with every journal rotation
1	Verify only the most important system and revision tables: <code>db.archmap, db.config, db.depot, db.graphindex, db.graphperm, db.group, db.groupx, db.integed, db.integtx, db.ldap, db.object, db.protect, db.pubkey, db.ref, db.rev, db.revcx, db.revdtx, db.revhx, db.revtx, db.stream, db.submodule, db.ticket, db.trigger, db.user</code>
2	Verify all database tables from level 1, plus: <code>db.bodtext, db.bodtextcx, db.bodtexthx, db.counters, db.excl, db.fix, db.fixrev, db.haveview, db.ixtext, db.ixtexthx, db.job, db.logger, db.message, db.nameval, db.property, db.remote, db.repo, db.revbtx, db.review, db.revsx, db.revux, db.rmtview, db.server, db.svrview, db.traits, db.uxtext</code>
3	Verify all metadata, including metadata that is likely to differ, especially when comparing an upstream server with a build-farm or edge-server replica.

Valid settings for `rpl.checksum.change` are:

<code>rpl.checksum.change</code>	Verification performed with each changelist
0	Perform no verification.
1	Write a journal note when a <code>p4 submit</code> , <code>p4 fetch</code> , <code>p4 populate</code> , <code>p4 push</code> , or <code>p4 unzip</code> command completes. The value of the <code>rpl.checksum.change</code> configurable will determine the level of verification performed for the command.
2	Replica verifies changelist summary, and writes to <code>integrity.csv</code> if the changelist does not match.
3	Replica verifies changelist summary, and writes to integrity log even when the changelist does match.

Valid settings for `rpl.checksum.table` are:

<code>rpl.checksum.table</code>	Level of table verification performed
0	Table-level checksumming only.

<code>rp1.checksum.table</code>	Level of table verification performed
1	When a table is unloaded or scanned, journal notes are written. These notes are processed by the replica and are logged to <code>integrity.csv</code> if the check fails.
2	When a table is unloaded or scanned, journal notes are written, and the results of journal note processing are logged even if the results match.

For more information, see `p4 help journaldbchecksums`.

Warnings, notes, and limitations

The following warnings, notes, and limitations apply to all configurations unless otherwise noted.

- On master servers, do not reconfigure these replica settings while the replica is running:
 - `P4TARGET`
 - `dm.domain.accessupdate`
 - `dm.user.accessupdate`
- Be careful not to inadvertently write to the replica's database. This might happen by using an `-r` option without specifying the full path (and mistakenly specifying the current path), by removing db files in `P4ROOT`, and so on. For example, when using the `p4d -r . -jc` command, make sure you are not currently in the root directory of the replica or standby in which `p4 journalcopy` is writing journal files.
- Large numbers of `Perforce password (P4PASSWD) invalid or unset` errors in the replica log indicate that the service user has not been logged in or that the `P4TICKETS` file is not writable.

In the case of a read-only directory or `P4TICKETS` file, `p4 login` appears to succeed, but `p4 login -s` generates the "invalid or unset" error. Ensure that the `P4TICKETS` file exists and is writable by the replica server.

- Client workspaces on the master and replica servers cannot overlap. Users must be certain that their `P4PORT`, `P4CLIENT`, and other settings are configured to ensure that files from the replica server are not synced to client workspaces used with the master server, and vice versa.
- Replica servers maintain a separate table of users for each replica; by default, the `p4 users` command shows only users who have used that particular replica server. (To see the master server's list of users, use `p4 users -c`).

The advantage of having a separate user table (stored on the replica in `db.user.rp`) is that after having logged in for the first time, users can continue to use the replica without having to repeatedly contact the master server.

- All server IDs must be unique. The examples in the section "[Configuring a build farm server](#)" on [page 52](#) illustrate the use of manually-assigned names that are easy to remember, but in very large environments, there may be more servers in a build farm than is practical to administer or remember. Use the command `p4 server -g` to create a new server specification with a numeric Server ID. Such a Server ID is guaranteed to be unique.

Whether manually-named or automatically-generated, it is the responsibility of the system administrator to ensure that the Server ID associated with a server's `p4 server` form corresponds exactly with the `server.id` file created (and/or read) by the `p4 serverid` command.

- Users of P4V and forwarding replicas are urged to upgrade to P4V 2012.1 or higher. Helix Server applications older than 2012.1 that attempt to use a forwarding replica can, under certain circumstances, require the user to log in twice to obtain two tickets: one for the first read (from the forwarding replica), and a separate ticket for the first write attempt (forwarded to the master) requires a separate ticket. This confusing behavior is resolved if P4V 2012.1 or higher is used.
- Although replicas can be chained together as of Release 2013.1, (that is, a replica's `P4TARGET` can be another replica, as well as from a central server), it is the administrator's responsibility to ensure that no loops are inadvertently created in this process. Certain multi-level replication scenarios are permissible, but pointless; for example, a forwarding replica of a read-only replica offers no advantage because the read-only replica will merely reject all writes forwarded to it. Please contact Perforce Technical Support for guidance if you are considering a multi-level replica installation.
- The `rpl.compress` configurable controls whether compression is used on the master-replica connection(s). This configurable defaults to `0`. Enabling compression can provide notable performance improvements, particularly when the master and replica servers are separated by significant geographic distances.

Enable compression with: `p4 configure set fwd-replica#rpl.compress=1`

Commit-edge

This topic assumes you have read the "Introduction to federated services" on page 9.

Note

You cannot issue the `p4 unsubmit` and `p4 resubmit` commands to an edge server. You can only issue these commands to a commit server.

Tip

Commit-edge architecture builds upon Helix Server replication technology. Before attempting to deploy a commit-edge configuration, read "Helix Server replication" on page 25, including the section on "Connecting services" on page 16, which includes information on "Managing SSL key pairs" on page 17.

Tip

An edge server can be used instead of a build farm server, and this usage is referred to as a *build edge server*. If the only users of an edge server are build processes, disaster recovery is possible without backing up the local edge server-specific workspace and related information. See "Migrating from existing installations" on page 73.

Important

Some Helix Core Server commands behave differently when you have edge servers. See the Support Knowledgebase article, "Edge Servers".

Setting up a commit/edge configuration

This section explains how you set up a commit/edge configuration. It assumes that you have an existing server that you want to convert to a commit server and that you are familiar with Helix Server management and operation. For the sake of this example, we'll assume that the existing server is in Chicago, and that we need to set up an edge server at a remote site in Tokyo.

- **Commit server**
`P4PORT=chicago.perforce.com:1666`
`P4ROOT=/chicago/p4root`
- **Edge server**
`P4PORT=tokyo.perforce.com:1666`
`P4ROOT=/tokyo/p4root`

The setup process includes the following major steps:

1. Create the service user accounts.
2. Configure the servers.
3. Create and start the servers.

You must have `super` privileges to perform these steps.

Tip

To improve performance, consider using the configurable `lbr.autocompress`.

See also the Support Knowledgebase [articles on performance](#).

Create service user accounts for the commit and edge server

To support secure communication between the commit server and the edge server, a user account of type service must be created. Although you can use a generic service user name for multiple edge servers, in this example we use a unique service user name for the one edge server.

1. Create service user accounts for the commit and edge servers:

```
$ p4 user -f svc_chicago_commit
$ p4 user -f svc_tokyo_edge
```

and in the user spec, set the user **Type:** field to **service**.

2. To prevent the service user logins from timing out, add the service users to a group with an unlimited timeout:

```
$ p4 group no_timeout
```

and in the **group** spec, set the **Users:** field to include the **svc_chicago_commit** and **svc_tokyo_edge** service users, and set the **Timeout:** field to **unlimited**.

3. Assign passwords to the service user accounts by providing a value at the prompts.

```
$ p4 passwd svc_chicago_commit
$ p4 passwd svc_tokyo_edge
```

4. In the protect spec, assign **super** protections to the **svc_chicago_commit** and **svc_tokyo_edge** service users.

```
$ p4 protect
super user svc_chicago_commit * //...
super user svc_tokyo_edge * //...
```

Next step

"Create commit and edge server configurations" below

Create commit and edge server configurations

Note

If your server version is prior to 2016.1, see the Knowledge Base article on "[Setting up a commit/edge server environment](#)".

The following steps are for server versions 2016.1 and later.

Note

It is best to set the **P4NAME** and **ServerID** to the same value: this makes it easy to isolate configuration variables on each server in a distributed environment.

Important

To avoid configuration problems, the value of `serverID` should always match the value of `P4NAME` if both are set. We recommend setting `serverID`, but support `P4NAME` for backward compatibility.

1. Create the commit server specification:

```
$ p4 server -c commit-server chicago_commit
```

and modify the `DistributedConfig` section to contain:

```
serviceUser=svc_chicago_commit
monitor=2
lbr.autocompress=1
journalPrefix=/chicago/backup/p4d_backup
P4TICKETS=/chicago/p4root/.p4tickets
P4LOG=/chicago/logs/chicago_commit.log
```

where:

- `serviceUser` is the name of the service user account that will be used for communication with edge servers
 - `monitor=2` enables monitoring of active commands and idle connections on this commit server with `p4 monitor show`
 - `lbr.autocompress=1` enables compressed storage for RCS file types on the commit server and is recommended in commit-edge environments for optimal archive file replication performance
 - `journalPrefix` is the prefix path used for the location and name of commit server checkpoints and rotated journals. When replicating metadata, edge servers periodically need to locate and read rotated commit server journals. The value of `journalPrefix` identifies the name and location of those journals.
 - `P4TICKETS` contains the path to the tickets file used by the commit server `serviceUser` when communicating with edge servers
 - `P4LOG` contains the path to the commit server's log file
2. Set the `server ID` of the commit server:

```
$ p4 serverid chicago_commit
```

3. Create the edge server specification:

```
$ p4 server -c edge-server tokyo_edge
```

and modify the `DistributedConfig` section to contain:

```

db.replication=readonly
lbr.replication=readonly
lbr.autocompress=1
rpl.compress=4
startup.1=pull -i 1
startup.2=pull -u -i 1
startup.3=pull -u -i 1
P4TARGET=chicago.perforce.com:1666
serviceUser=tokyo_edge
monitor=1
journalPrefix=/tokyo/backup/p4d_backup
P4TICKETS=/tokyo/p4root/.p4tickets
P4LOG=/tokyo/logs/tokyo_edge.log

```

where

- The `db.replication=readonly` and `lbr.replication=readonly` values indicate the edge server will replicate metadata and archive data from the commit server
- `lbr.autocompress=1` enables compressed storage for RCS file types on this edge server and is recommended in commit-edge environments for optimal archive file replication performance
- `rpl.compress=4` enables compression of journal data sent by the commit server to this edge server and is recommended if the edge server is remote to the commit server
 - For edge servers that are local to the commit server, compression can be disabled by removing the `rpl.compress=4` from the `DistributedConfig` before saving
- The `startup.N` values define one metadata (`pull -i 1`) and two archive (`pull -u -i 1`) pull threads that the edge server will run on startup to facilitate metadata and archive replication
- `P4TARGET` specifies the `P4PORT` (host:port) of the commit server this edge server will replicate from
- `serviceUser` is the name of the service user account that will be used for communication with commit server
- `monitor=1` enables monitoring of active commands on this edge server with `p4 monitor show`
- `journalPrefix` is the prefix path used for the location and name of edge server checkpoints and rotated journals
- `P4TICKETS` contains the path to the tickets file used by the edge server `serviceUser` when communicating with the commit server
- `P4LOG` contains the path to the server log file used by the edge server

Next step

"Create and start the edge servers" on the next page

Create and start the edge servers

Now that the commit server configuration is complete, we can seed the edge server from a commit server checkpoint and complete a few more steps to create it.

1. Take a checkpoint of the commit server, and use `-K` to filter out the database content not needed by an edge server. (The `-z` flag creates a zipped checkpoint.)

```
$ p4d -r /chicago/p4root -K
"db.have,db.working,db.locks,db.resolve,db.revsh,db.workingx,
db.resolvex,db.stash,db.haveg,db.workingg,db.locksg,db.resolv
eg" -z -jd edge.ckp
```

2. Recover the zipped checkpoint into the edge server `P4ROOT` directory.

```
$ p4d -r /tokyo/p4root -z -jr edge.ckp.gz
```

3. Set the server ID for the newly seeded edge server:

```
$ p4d -r /tokyo/p4root -xD tokyo_edge
```

4. To enable the tokyo edge service user to connect to the chicago commit server, create a login ticket for the `svc_tokyo_edge` service user in the `P4TICKETS` file configured for the tokyo edge server:

```
$ p4 -E P4TICKETS=/tokyo/p4root/.p4tickets -u svc_tokyo_edge
-p chicago.perforce.com:1666 login
```

- Copy the versioned files from the commit server to the edge server. Files and directories can be moved using `rsync`, `tar`, `ftp`, a network copy, or any other method that preserves the files as they were on the original server.

For Linux:

Run `rsync` (or the equivalent):

```
cd /chicago/p4root rsync -avz ./depo
performer@tokyo.perforce.com:/tokyo/p4root
```

where

- `/chicago/p4root` is the commit server root
- `./depo` is one of the directories to be copied on the original server
- `performer@tokyo.perforce.com` is the user and hostname of the new edge server
- `/tokyo/p4root` is the Helix Server root directory on the new edge server

Copy over all the versioned file directories.

For Windows:

Run `xcopy` (or the equivalent):

```
cd <Perforce original root>
cd depot
xcopy *.* S:\perforce /s /d /c /e /i /h /y
```

where

`S:\perforce` is the network drive that contains the corresponding directory on the new server.

Copy over all the versioned file directories.

Note

For Linux and Windows:

- It is possible to copy most of the files before the server move, then update the versioned files later. To update the versioned files, run the same `rsync` command. The `rsync` flags used by this command will only transfer files updated since the command was last run.
- If you do not know where the versioned files are located, run the command: `p4 depots`. For each depot listed, run the command: `p4 depot -o depot` and look at the **Map:** field for the depot versioned files location.

6. Start the edge server using syntax appropriate for your platform.

For example:

```
$ p4d -r /tokyo/p4root -d
```

See the installation/upgrading instructions for [UNIX](#) and [Windows](#) in the "Installing and Upgrading the Server" chapter of the *Helix Core Server Administrator Guide: Fundamentals*.

7. Check the status of replication by running the following command against the edge server.

```
$ p4 pull -lj
```

8. At the commit server host machine, to enable the chicago commit service user to connect to the tokyo edge server, create a login ticket for the `svc_chicago_commit` service user in the `P4TICKETS` file configured for the chicago commit server:

```
$ p4 -E P4TICKETS=/chicago/p4root/.p4tickets -u svc_chicago_
commit -p tokyo.perforce.com:1666 login
```

Client workspaces and client views

Binding workspaces to the edge server

Bind client workspaces to the edge server.

Because this server is configured to offer the edge server service, it maintains its own local copy of the list of client workspaces (`db.view`) and their respective have lists (`db.have`).

On the edge server, create a client workspace with `p4 client`:

```
$ p4 -c edge0001 -p edge:1667 client edge0001
```

When creating a new workspace on the edge server, you must ensure that your current client workspace has a `ServerID` that matches that required by `edge:1667`. Because workspace `edge0001` does not yet exist, you must manually specify `edge0001` as the current client workspace with the `-c clientname` option and simultaneously supply `edge0001` as the argument to the `p4 client` command.

When the `p4 client` form appears, set the `ServerID:` field to `edge-1667` and note that if it is not set manually, it will be set automatically when the form is saved.

Setting global client views

The `server.global.client.views` configurable determines whether the view maps of a non-stream client on an edge server are made global when the client is modified. This configurable can be set globally or individually for each server, thus allowing client maps to be global on most edge servers while keeping them local on those edge servers that don't need or want them to be global.

The value of `server.global.client.views` on an edge server determines whether it forwards view maps to a commit server.

You should make client view maps on a replica global if up-to-date information is needed by another server running a command that needs a client view map; for example, if that client is to be used as a template on another server.

- If `server.global.client.views=1` on an edge server, then when a client is modified on that edge server, its view map is made global.
- The default value of `0` on the edge server means that client view maps on that edge server are not made global when a client is modified.

Setting this configurable does not immediately make client view maps global; that happens only when a client is modified afterwards. Clearing this configurable does not delete the view maps of any clients, but it does prevent subsequent changes to a client's view map from being propagated to other servers. If a client with global view maps is deleted, its view maps are also deleted globally regardless of the value of `server.global.client.views`; this is to prevent orphaned view maps.

In summary, view maps of a client are made global only under these conditions:

- The client is bound to an edge server.
- The edge server has `server.global.client.views=1`.
- The client is a non-stream client.
- The client is modified.

If you are working with an existing client, you can "modify" it by adding a few words to the description. For example, you can add a statement that this client's view maps are now global.

Note

Clients bound directly to a commit server have their view maps replicated everywhere independently of the setting of `server.global.client.views`.

For complicated reasons, it is best to choose one setting for this configurable, and not change it.

Creating a client from a template

You might want to create a client from a template when you want to create a client that is similar to an existing client (especially the view map). For example, you want to create a client that maps the mainline server code so that you can build it yourself. This might require multiple view map entries, so you want to base your client on one that already has those view maps defined.

Clients created on a commit server can be used as templates by clients created on the commit server or on any edge server.

A client bound to an edge server can be used as a template for clients on that same edge server. To use it as a template on a different edge server or on the commit server, its view map should be global (that is, copied to the commit server).

A client's view map is made global when the client is modified and `server.global.client.views=1` on both the edge server to which it is bound and on the commit server. You can create a client for an edge server or commit server based on an existing client template (bound to a different edge server) using a command like the following:

```
$ p4 client -t clientBoundToOtherEdge clientBoundToMyEdge
```

The newly created client will have its **View** map copied from the **View** map of the template client, with the client name on the right-hand side entries changed from the template client name (`clientBoundToOtherEdge`) to the new client name (`clientBoundToMyEdge`).

Migrating from existing installations

The following sections explain how you migrate to an edge-commit architecture from an existing replicated architecture.

- ["Replacing existing proxies and replicas" below](#) explains what sort of existing replicates can be profitably replaced with edge servers.
- ["Deploying commit and edge servers incrementally" on the facing page](#) describes an incremental approach to migration.
- ["Hardware, sizing, and capacity" on the facing page](#) discusses how provisioning needs shift as you migrate to the edge-commit architecture.
- ["Migration scenarios" on page 75](#) provides instructions for different migration scenarios.

Replacing existing proxies and replicas

If you currently use a Helix Proxy, evaluate whether it should be replaced with an edge server. If a proxy is delivering acceptable performance, then it can be left in place indefinitely. You can use proxies in front of edge servers if necessary. Deploying commit and edge servers is notably more complex than deploying a master server and proxy servers. Consider your environment carefully.

Of the three types of replicas available, forwarding replicas are the best candidates to be replaced with edge servers. An edge server provides a better solution than a forwarding replica for many use cases.

Build replicas can be replaced if necessary. If your build processes need to issue write commands other than `p4 sync`, an edge server is a good option. But if your build replicas are serving adequately, then you can continue to use them indefinitely.

Read-only replicas, typically used for disaster recovery, can remain in place. You can use read-only replicas as part of a backup plan for edge servers.

Deploying commit and edge servers incrementally

You can deploy commit and edge servers incrementally. For example, an existing master server can be reconfigured to act as a commit server, and serve in hybrid mode. The commit server continues to service all existing users, workspaces, proxies, and replicas with no change in behavior. The only immediate difference is that the commit server can now support edge servers.

Once a commit server is available, you can proceed to configure one or more edge servers. Deploying a single edge server for a pilot team is a good way to become familiar with edge server behavior and configuration.

Additional edge servers can be deployed periodically, giving you time to adjust any affected processes and educate users about any changes to their workflow.

Initially, running a commit server and edge server on the same machine can help achieve a full split of operations, which can make subsequent edge server deployments easier.

Hardware, sizing, and capacity

For an initial deployment of a distributed Perforce service, where the commit server acts in a hybrid mode, the commit server uses your current master server hardware. Over time, you might see the performance load on the commit server drop as you add more edge servers. You can reevaluate commit server hardware sizing after the first year of operation.

An edge server handles a significant amount of work for users connected to that edge server. A sensible strategy is to repurpose an existing forwarding replica and monitor the performance load on that hardware. Repurposing a forwarding replica involves the following:

- Reconfiguring the forwarding replica as an edge server.
- Creating new workspaces on the edge server or transferring existing workspaces to the edge server. Existing workspaces can be transferred using `p4 unload` and `p4 reload` commands. See "[Migrating a workspace from a commit server or remote edge server to the local edge server](#)" on page 77 for details.

As you deploy more edge servers, you have the option to deploy fewer edge servers on more powerful hardware, or to deploy more edge servers, each using less powerful hardware, to service a smaller number of users.

You can also take advantage of replication filtering to reduce the volume of metadata and archive content on an edge server.

Note

An edge server maintains a unique copy of local workspace metadata, which is not shared with other edge servers or with the commit server.

Filtering edge server content can reduce the demands for storage and performance capacity.

As you transition to commit-edge architecture and the commit server is only handling requests from edge servers, you may find that an edge server requires more hardware resources than the commit server.

Migration scenarios

This section provides instructions for several migration scenarios. If you do not find the material you need, email support@perforce.com.

Configuring a master server as a commit server

Scenario: You have a master server. You want to convert your master to a commit server, allowing it to work with edge servers as well as to continue to support clients.

1. Choose a ServerID for your master server, if it does not have one already, and use `p4 serverid` to save it.
2. Define a server spec for your master server or edit the existing one if it already has one, and set `Services: commit-server`.

Converting a forwarding replica to an edge server

Scenario: You currently have a master server and a forwarding replica. You want to convert your master server to a commit server and convert your forwarding replica to an edge server.

Depending on how your current master server and forwarding replica are set up, you may not have to do all of these steps.

1. Have all the users of the forwarding replica either submit, shelve, or revert all of their current work, and have them delete their current workspaces.
2. Stop your forwarding replica.
3. Choose a ServerID for your master server, if it does not have one already, and use `p4 serverid` to save it.
4. Define a server spec for your master server, or edit the existing one if it already has one, and set `Services: commit-server`.
5. Use `p4 server` to update the server spec for your forwarding replica, and set `Services: edge-server`.

6. Update the replica server with your central server data by doing one of the following:
 - Use a checkpoint:
 - a. Take a checkpoint of your central server, filtering out the `db.have`, `db.working`, `db.resolve`, `db.locks`, `db.revsh`, `db.workingx`, `db.resolvex` tables.

```
$ p4d -K
"db.have,db.working,db.resolve,db.locks,db.revsh,db.w
orkingx,db.resolvex"
-jd my_filtered_checkpoint_file
```

Tip
If you want to produce a filtered journal dump file, go to [Helix Core Server Administrator Guide: Fundamentals](#), and look in the "Helix Core Server Reference" for the `-k` and `-K` options.
 - b. Restore that checkpoint onto your replica.
 - c. It is good practice, but it is not required that you remove the replica's state file.
 - Use replication:
 - a. Start your replica on a separate port (so local users don't try to use it yet).
 - b. Wait for it to pull the updates from the master.
 - c. Stop the replica and remove the `db.have`, `db.working`, `db.resolve`, `db.locks`, `db.revsh`, `db.workingx`, `db.resolvex` tables.
7. Start the replica; it is now an edge server.
8. Have the users of the old forwarding replica start to use the new edge server:
 - Create their new client workspaces and sync them.

You are now up and running with your new edge server.

Converting a build server to an edge server

Scenario: You currently have a master server and a build server. You want to convert your master server to a commit server and convert your build server to an edge server.

Build servers have locally-bound clients already, and it seems very attractive to be able to continue to use those clients after the conversion from a build-server to an edge server. There is one small detail:

- On a build server, locally-bound clients store their *have* and *view* data in `db.have.rp` and `db.view.rp`.
- On an edge server, locally-bound clients store their *have* and *view* data in `db.have` and `db.view`.

Therefore the process for converting a build server to an edge server can be the following :

1. Define a ServerID and server spec for the master, setting `Services: commit-server`.
2. Edit the server spec for the build-server and change `Services: build-server` to `Services: edge-server`.
3. Shut down the build-server and do the following:

```
$ rm db.have db.view db.locks db.working db.resolve db.revsh
db.workingx db.resolvex
$ mv db.have.rp db.have
$ mv db.view.rp db.view
```

4. Start the server; it is now an edge server and all of its locally-bound clients can continue to be used.

Note

Step 3 above discards the `db.view` table, but there are multiple possibilities:

1. Retain `db.view`, Discard `db.view.rp`.
This means the edge server will discard all pre-existing build clients and need to create them in the edge server.
2. Retain `db.view.rp`, Discard `db.view`.
This means the edge server will have access to pre-existing build clients, but the other clients that were previously accessible in the build farm become inaccessible.
3. Retain both `db.view` and `db.view.rp`.
If you want to maintain the same access of all available clients, including the build clients, please contact Technical Support.

Migrating a workspace from a commit server or remote edge server to the local edge server

Scenario: You have a workspace on a commit or remote edge server that you want to move to the local edge server.

1. Current work may be unsubmitted and/or shelved.
2. Execute the following command against the local edge server, where the workspace is being migrated to. `protocol:host:port` refers to the commit or remote edge server the workspace is being migrated from.

```
$ p4 reload -c workspace -p protocol:host:port
```

Managing distributed installations

Commit-edge architecture raises certain issues that you must be aware of and learn to manage.

- Each edge server maintains a unique set of workspace and work-in-progress data that must be backed up separately from the commit server. See ["Backup and high availability/disaster recovery \(HA/DR\) planning" on page 83](#) for more information.
- Exclusive locks are global: establishing an exclusive lock requires communication with the commit server, which might incur network latency.
- Parallel submits from an edge server to a commit server use standard pull threads to transfer the files. The administrator must ensure that pull threads can be run on the commit server by doing the following:
 - Make sure that the service user used by the commit server is logged into the edge server.
 - Make sure the `ExternalAddress` field of the edge server's server spec is set to the address that will be used by the commit server's pull threads to connect to the edge server.

If the commit and edge servers communicate on a network separate from the network used by clients to communicate with the edge server, the `ExternalAddress` field must specify the edge server ip address and port number that is used for connections from the commit server. Furthermore, the edge server must listen on the two (or more) networks.

See the `p4 help submit` command for more information.

- Shelving changes in a distributed environment typically occurs on an edge server. Shelving can occur on a commit server only while using a client workspace bound to the commit server. Normally, changelists shelved on an edge server are not shared between edge servers.

You can promote changelists shelved on an edge server to the commit server, making them available to other edge servers. See ["Promoting shelved changelists" on the next page](#) for details.

- Auto-creation of users is not possible on edge servers.
- You must use a command like the following to delete a client that is bound to an edge server: It is not sufficient to simply use the `-d` and `-f` options.

```
$ p4 client -d -f --serverid=thatserver thatclient
```

This prevents your inadvertently deleting a client from an edge server. Likewise, you must specify the server id and the changelist number when trying to delete a changelist whose client is bound to an edge server.

```
$ p4 change -d -f --serverid=thatserver 6321
```

Moving users to an edge server

As you create new edge servers, you assign some users and groups to use that edge server.

- Users need the `P4PORT` setting for the edge server.
- Users need to create a new workspace on the edge server or to transfer an existing workspace to the new edge server. Transferring existing workspaces can be automated.

If you use authentication triggers or single sign-on, install the relevant triggers on all edge servers and verify the authentication process.

Promoting shelved changelists

Changelists shelved on an edge server, which would normally be inaccessible from other edge servers, can be automatically or explicitly *promoted* to the commit server. Promoted shelved changelists are available to any edge server.

- In a shared archive configuration, where the commit server and edge servers have access to the same storage device for the archive content, shelves are automatically promoted to the commit server. For more information, see ["Automatically promoting shelves" below](#).
- You must explicitly promote a shelf when the commit and edge servers do not share the archive. For more information, see ["Explicitly promoting shelves" below](#).

You can view a shelf's promotion status using the `-ztag` output of the `p4 describe`, `p4 changes`, or `p4 change -o` commands.

See ["Working with promoted shelves" on the facing page](#) for more information on the limitations of working on promoted shelves.

Automatically promoting shelves

When the edge server and commit server are configured to access the same archive contents, shelf promotion occurs automatically, and promoting shelved fields with `p4 shelve -p` is not required.

To configure the edge server and commit server to access the same archive contents, you should set `server.depot.root` to the same path for both the commit and edge server, and you should set the `lbr.replication` configurable to `shared` for the edge server. For example:

```
$ p4 configure set commit#server.depot.root=/p4/depot/root
$ p4 configure set edge#server.depot.root=/p4/depot/root
$ p4 configure set edge#lbr.replication=shared
```

Explicitly promoting shelves

You have two ways of explicitly promoting shelves:

- Set the `dm.shelve.promote` configurable: `dm.shelve.promote=1`.
This makes edge servers always promote shelved files to the commit server, which means that file content is transferred and stored both on the commit server and the edge server. (Generally, it is a bad idea to enable automatic promotion because it causes unnecessary file transfers for shelved files that are not meant to be shared.)
- Use the `-p` option with the `p4 shelve` command.
See the example below for more information on this option.

For example, given two edge servers, `edge1` and `edge2`:

1. Shelve and promote a changelist from `edge1`.

```
edge1$ p4 shelve -p -c 89
```

2. The shelved changelist is now available to `edge2`.

```
edge2$ p4 describe -S 89
```

3. Promotion is only required once.

Subsequent `p4 shelve` commands automatically update the shelved changelist on the commit server, using server lock protection. For example, make changes on `edge1` and refresh the shelved changelist:

```
edge1$ p4 shelve -r -c 89
```

The updates can now be seen on `edge2`:

```
edge2$ p4 describe -S 89
```

Promoting shelves when unloading clients

Use the `-p` option for the `p4 unload` command to promote any non-promoted shelves belonging to the specified client that is being unloaded. The shelf is promoted to the commit server where it can be accessed by other edge servers.

Working with promoted shelves

You can:

- delete the shelved files from the changelist, but you cannot unpromote a shelved changelist
- unshelve a promoted shelf into open files and branches on a server from where the shelf did not originate
- run `p4 submit -e` on a promoted shelf only on the server that owns the change
- move a promoted shelf from one edge server to another using the `p4 unshelve` command

Locking and unlocking files

You can use the `-g` flag of the `p4 lock` command to lock the files locally and globally. The `-g` option must be used with the `-c changelist` option. This lock is removed by the `p4 unlock -g` command or by any submit command for the specified changelist.

Use the `-x` option to the `p4 unlock` command to unlock files that have the `+1` filetype (exclusive open) but have become orphaned. This is typically only necessary in the event of an extended network outage between an edge server and the commit server.

To make `p4 lock` on an edge server take global locks on the commit server by default, set the `server.locks.global` configurable to `1`. See the section [Configurables](#) in [P4 Command Reference](#).

Triggers

This section explains how you manage existing triggers in a commit-edge configuration and how you use edge type triggers.

Determining the location of triggers

In a distributed Perforce service, triggers might run either on the commit server, or on the edge server, or perhaps on both. For more information on triggers, see the [Helix Core Server Administrator Guide: Fundamentals](#).

Make sure that all relevant trigger scripts and programs are deployed appropriately. Edge servers can affect non-edge type triggers in the following ways:

- If you enforce policy with triggers, you should evaluate whether a change list or shelve trigger should execute on the commit server or on the edge server.
- Edge servers are responsible for running form triggers on workspaces and some types of labels.

Tip

Read about the sequence of triggers that run during an edge server submit in the Support Knowledgebase article, "[Triggers in a Distributed Perforce Environment](#)".

Trigger scripts can determine whether they are running on a commit or edge server using the trigger variables described in the following table. When a trigger is executed on the commit server, `%peerip%` matches `%clientip%`.

Trigger Variable	Description
<code>%peerip%</code>	The IP address of the proxy, broker, replica, or edge server.

Trigger Variable	Description
<code>%clientip%</code>	The IP address of the machine whose user invoked the command, regardless of whether connected through a proxy, broker, replica, or edge server.
<code>%submitserverid%</code>	For a <code>change-submit</code> , <code>change-content</code> , or <code>change-commit</code> trigger in a distributed installation, the <code>server.id</code> of the edge server where the submit was run. See <code>p4 serverid</code> in the P4 Command Reference for details.

Using edge triggers

In addition, edge servers support two trigger types that are specific to edge-commit architecture: `edge-submit` and `edge-content`:

Trigger Type	Description
<code>edge-submit</code>	Executes a <code>pre-submit</code> trigger on the edge server after changelist has been created, but prior to file transfer from the client to the edge server. The files are not necessarily locked at this point.
<code>edge-content</code>	Executes a <code>mid-submit</code> trigger on the edge server after file transfer from the client to the edge server, but prior to file transfer from the edge server to the commit server. At this point, the changelist is shelved.

Triggers on the edge server are executed one after another when invoked via `p4 submit -e`. For `p4 submit`, `edge-submit` triggers run immediately before the changelist is shelved, and `edge-content` triggers run immediately after the changelist is shelved.

Because `edge-submit` triggers run prior to file transfer to the edge server, these triggers cannot access file content.

The following `edge-submit` trigger is an MS-DOS batch file that rejects a changelist if the submitter has not had the change reviewed and approved. This trigger fires only on changelist submission attempts that affect at least one file in the `//depot/qa` branch.

```
@echo off
rem REMINDERS
rem - If necessary, set Perforce environment vars or use config file
rem - Set PATH or use full paths (C:\PROGRA~1\Perforce\p4.exe)
rem - Use short pathnames for paths with spaces, or quotes
rem - For troubleshooting, log output to file, for instance:
rem - C:\PROGRA~1\Perforce\p4 info >> trigger.log
if not x%1==x goto doit
```

```
echo Usage is %0[change#]
:doit
p4 describe -s %1|findstr "Review Approved...\n\n\t" > nul
if errorlevel 1 echo Your code has not been reviewed for changelist %1
p4 describe -s %1|findstr "Review Approved...\n\n\t" > nul
```

To use the trigger, add the following line to your triggers table:

```
sampleEdge    edge-submit //depot/qa/...    "reviewcheck.bat %changelist%"
```

Backup and high availability/disaster recovery (HA/DR) planning

A commit server can use the same backup and HA/DR strategy as a master server. Edge servers contain unique information and should have a backup and an HA/DR plan. Whether an edge server outage is as urgent as a master server outage depends on your requirements. An edge server might have an HA/DR plan with a less ambitious Recovery Point Objective (RPO) and Recovery Time Objective (RTO) than the commit server.

If a commit server must be rebuilt from backups, each edge server must be rolled back to a backup prior to the commit server's backup.

Alternatively, if your commit server has no local users, the commit server can be rebuilt from a fully-replicated edge server. In this scenario, the edge server is a superset of the commit server.

Backing up and recovering an edge server is similar to backing up and restoring an offline replica server:

1. On the edge server, schedule a checkpoint to be taken the next time journal rotation is detected on the commit server. For example:

```
$ p4 -p myedgehost:myedgeport admin checkpoint
```

The **p4 pull** command performs the checkpoint at the next rotation of the journal on the commit server. A **stateCKP** file is written to the **P4ROOT** directory of the edge server, recording the scheduling of the checkpoint.

2. Rotate the journal on the commit server:

```
$ p4 -p mycommithost:mycommitport admin journal
```

As long as the edge server's replication state file is included in the backup, the edge server can be restored and resume service. If the edge server was offline for a long period of time, it might need to catch up on the activity on the commit server.

As part of a failover plan for a commit server, make sure that the edge servers are redirected to use the new commit server.

Note

For commit servers with no local users, edge servers could take significantly longer to checkpoint than the commit server. You might want to use a different checkpoint schedule for edge servers than commit servers. If you use several edge servers for one commit server, you should stagger the edge-checkpoints so they do not all occur at once and bring the system to a stop. Journal rotations for edge servers could be scheduled at the same time as journal rotations for commit servers.

Other considerations

As you deploy edge servers, give consideration to the following areas.

■ Labels

In a distributed Perforce service, labels can be local to an edge server or global.

- By default, labels are also bound to the Edge Server on which they are created.
- The `-g` flag defaults to the value of `0`, which indicates that the label is to be defined globally on all servers in the installation. Configuring `rpl.labels.global=1` allows updating of local labels. See `rpl.labels.global` in the [P4 Command Reference](#).
- For important details, on the command line, type `p4 help distributed`.

■ Exclusive Opens

Exclusive opens (`+1` filetype modifier) are global: establishing an exclusive open requires communication with the commit server, which may incur network latency.

■ Integrations with third party tools

If you integrate third party tools, such as defect trackers, with Helix Server, evaluate whether those tools should continue to connect to the master/commit server or could use an edge server instead. If the tools only access global data, then they can connect at any point. If they reference information local to an edge server, like workspace data, then they must connect to specific edge servers.

Build processes can usefully be connected to a dedicated edge server, providing full Helix Server functionality while isolating build workspace metadata. Using an edge server in this way is similar to using a build farm replica, but with the additional flexibility of being able to run write commands as part of the build process.

■ Files with propagating attributes

In distributed environments, the following commands are not supported for files with propagating attributes: `p4 copy`, `p4 delete`, `p4 edit`, `p4 integrate`, `p4 reconcile`, `p4 resolve`, `p4 shelve`, `p4 submit`, and `p4 unshelve`. Integration of files with propagating attributes from an edge server is not supported; depending on the integration action, target, and source, either the `p4 integrate` or the `p4 resolve` command will fail.

If your site makes use of this feature, direct these commands to the commit server, not the edge server. Perforce-supplied software does not presently set propagating attributes on files and is not known to be affected by this limitation.

■ Logging and auditing

Edge servers maintain their own set of server and audit logs. Consider using structured logs for edge servers, as they auto-rotate and clean up with journal rotations. Incorporate each edge server's logs into your overall monitoring and auditing system.

In particular, consider the use of the `rpl.checksum.*` configurables to automatically verify database tables for consistency during journal rotation, changelist submission, and table scans and unloads. Regularly monitor the `integrity.csv` structured log for integrity events.

■ Unload depot

The unload depot might have different contents on each edge server. Clients and labels bound to an edge server are unloaded into the unload depot on that edge server, and are not displayed by the `p4 clients -U` and `p4 labels -U` commands on other edge servers.

Be sure to include the unload depot as part of your edge server backups. The commit server does not verify that the unload depot is empty on every edge server. Therefore, to delete the unload depot from the commit server, `p4 depot -d -f` is the command.

■ Future upgrades

Commit and edge servers should be upgraded at the same time.

■ Time zones

Commit and edge servers must use the same time zone.

■ Helix Swarm

The initial release of Swarm can usefully be connected to a commit server acting in hybrid mode or to an edge server for the users of that edge server. Full Swarm compatibility with multiple edge servers will be handled in a follow-on Swarm release. For more detailed information about using Swarm with edge servers, please contact Perforce Technical Support support@perforce.com.

Validation

As you deploy commit and edge servers, you can focus your testing and validation efforts in the following areas.

Supported deployment configurations

- Hybrid mode: commit server also acting as a regular master server
- Read-only replicas attached to commit and edge servers
- Proxy server attached to an edge server

Backups

Exercise a complete backup plan on the commit and edge servers. Note that journal rotations are not permitted directly on an edge server. Journal rotations can occur on edge servers as a consequence of occurring on a master server.

Helix Broker

This topic assumes you have read the "Introduction to federated services" on page 9.

The work needed to install and configure a broker is minimal: the administrator needs to configure the broker and configure the users to access the Helix Server through the broker. Broker configuration involves the use of a configuration file that contains rules for specifying which commands individual users can execute and how commands are to be redirected to the appropriate Perforce service. You do not need to back up the broker. In case of failure, you just need to restart it and make sure that its configuration file has not been corrupted.

From the perspective of the end user, the broker is transparent: users connect to a Helix Broker just as they would connect to any other Helix Core Server.

System requirements	87
Installing the broker	87
Running the broker	88
Enabling SSL support	89
Broker information	89
Broker and protections	90
P4Broker options	91
Configuring the broker	92
Format of broker configuration files	93
Specifying hosts	93
Global settings	94
Command handler specifications	97
Alternate server definitions	103
Using the broker as a load-balancing router	103
Configuring the broker as a router	104
Routing policy and behavior	104

System requirements

To use the Helix Broker, you must have:

- A Helix Server (p4d) at release 2007.2 or higher (2012.1 or higher to use SSL).
- Helix Server applications at release 2007.2 or higher (2012.1 or higher to use SSL).

The Helix Broker is designed to run on a host that lies close to the Helix Server, preferably on the same machine.

Installing the broker

To install P4Broker, do the following:

1. Download the `p4broker` executable from the Perforce website,
2. Copy it to a suitable directory on the host (such as `/usr/local/bin`), and ensure that the binary is executable:

```
$ chmod +x p4broker
```

Running the broker

After you have created your configuration file (see "Configuring the broker" on page 92), start the Helix Broker from the command line by issuing the following command:

```
$ p4broker -c config_file
```

Alternatively, you can set `P4BROKEROPTIONS` before launching the broker and use it to specify the broker configuration file (or other options) to use.

For example, on Unix:

```
$ export P4BROKEROPTIONS="-c /usr/perforce/broker.conf"
$ p4broker -d
```

and on Windows:

```
C:\> p4 set -s P4BROKEROPTIONS="-c c:\p4broker\broker.conf"
C:\> p4broker
```

The Helix Broker reads the specified broker configuration file, and on Unix platforms the `-d` option causes the Helix Broker to detach itself from the controlling terminal and run in the background.

To configure the Helix Broker to start automatically, create a startup script that sets `P4BROKEROPTIONS` and runs the appropriate `p4broker` command.

On Windows systems, you can also set `P4BROKEROPTIONS` and run the broker as a service. This involves the following steps:

```
C:\> cd C:\p4broker\
C:\p4broker\> copy p4broker.exe p4brokers.exe
C:\p4broker\> copy "C:\Program Files\Perforce\Server\svcinst.exe"
svcinst.exe
C:\p4broker\> svcinst create -n P4Broker -e
"C:\p4broker\p4brokers.exe" -a
C:\p4broker\> p4 set -S P4Broker P4BROKEROPTIONS="-c
C:\p4broker\p4broker.conf"
C:\p4broker\> svcinst start -n P4Broker
```

`svcinst.exe` is a standard Windows program. **P4Broker** is the name given to the Windows service. For more information, see the Knowledge Base article, "[Installing P4Broker on Windows and Unix systems](#)".

Enabling SSL support

To encrypt the connection between a Helix Broker and its end users, your broker must have a valid private key and certificate pair in the directory specified by its **P4SSLDIR** environment variable. Certificate and key generation and management for the broker works the same as it does for the Helix Core Server. See "[Enabling SSL support](#)" on page 36. The users' Helix Server applications must be configured to trust the fingerprint of the broker.

To encrypt the connection between a Helix Broker and a Helix Core Server, your broker must be configured so as to trust the fingerprint of the Helix Core Server. That is, the user that runs **p4broker** (typically a service user) must create a **P4TRUST** file (using **p4 trust**) that recognizes the fingerprint of the Helix Core Server, and must set **P4TRUST**, specifying the path to that file (**P4TRUST** cannot be specified in the broker configuration file).

For more information about enabling SSL for the broker, see the Support Knowledgebase article, "[Enabling SSL Support for the Server/Broker/Proxy](#)".

Broker information

You can issue the **p4 info** to determine whether you are connected to a broker or not. When connected to a broker, the **Broker address** and **Broker version** appear in the output:

```
$ p4 info
User name: bruno
Client name: bruno-ws
Client host: bruno.host
Client root: /Users/bruno/Workspaces/depot
Current directory: /Users/bruno/Workspaces/depot/main/jam
Peer address: 192.168.1.40:55138
Client address: 192.168.1.114
Server address: perforce:1667
Server root: /perforce/server/root
Server date: 2014/03/13 15:46:52 -0700 PDT
Server uptime: 92:26:02
Server version: P4D/LINUX26X86_64/2014.1/773873 (2014/01/21)
ServerID: master-1666
Broker address: perforce:1666 Broker version:
P4BROKER/LINUX26X86_64/2014.1/782990
```

```
Server license: 10000 users (support ends 2016/01/01)
Server license-ip: 192.168.1.40
Case Handling: sensitive
```

When connected to a broker, you can use the **p4 broker** command to see a concise report of the broker's info:

```
$ p4 broker
Current directory: /Users/bruno/Workspaces/depot/main/jam
Client address: 192.168.1.114:65463
Broker address: perforce:1666
Broker version: P4BROKER/LINUX26X86_64/2014.1/782990
```

Broker and protections

To apply the IP address of a broker user's workstation against the protections table, prepend the string **proxy-** to the workstation's IP address.

Important

Before you prepend the string **proxy-** to the workstation's IP address, make sure that a broker or proxy is in place.

For instance, consider an organization with a remote development site with workstations on a subnet of **192.168.10.0/24**. The organization also has a central office where local development takes place; the central office exists on the **10.0.0.0/8** subnet. A Perforce service resides in the **10.0.0.0/8** subnet, and a broker resides in the **192.168.10.0/24** subnet. Users at the remote site belong to the group **remotedev**, and occasionally visit the central office. Each subnet also has a corresponding set of IPv6 addresses.

To ensure that members of the **remotedev** group use the broker while working at the remote site, but do not use the broker when visiting the local site, add the following lines to your protections table:

```
list    group    remotedev    192.168.10.0/24    -//...
list    group    remotedev    [2001:db8:16:81::]/48    -//...

write   group    remotedev    proxy-192.168.10.0/24    //...
write   group    remotedev    proxy-[2001:db8:16:81::]/48    //...

list    group    remotedev    proxy-10.0.0.0/8    -//...
list    group    remotedev    proxy-[2001:db8:1008::]/32    -//...
```

```
write group remotedev 10.0.0.0/8 //...
write group remotedev [2001:db8:1008::]/32 //...
```

The first line denies **list** access to all users in the **remotedev** group if they attempt to access Helix Server without using the broker from their workstations in the **192.168.10.0/24** subnet. The second line denies access in identical fashion when access is attempted from the IPV6 **[2001:db8:16:81::]/48** subnet.

The third line grants **write** access to all users in the **remotedev** group if they are using the broker and are working from the **192.168.10.0/24** subnet. Users of workstations at the remote site must use the broker. (The broker itself does not have to be in this subnet, for example, it could be at **192.168.20.0**.) The fourth line grants access in identical fashion when access is attempted from the IPV6 **[2001:db8:16:81::]/48** subnet.

Similarly, the fifth and sixth lines deny **list** access to **remotedev** users when they attempt to use the broker from workstations on the central office's subnets (**10.0.0.0/8** and **[2001:db8:1008::]/32**). The seventh and eighth lines grant write access to **remotedev** users who access the Helix Server directly from workstations on the central office's subnets. When visiting the local site, users from the **remotedev** group must access the Helix Server directly.

When the Perforce service evaluates protections table entries, the **dm.proxy.protects** configurable is also evaluated.

dm.proxy.protects defaults to **1**, which causes the **proxy-** prefix to be prepended to all client host addresses that connect via an intermediary (proxy, broker, broker, or edge server), indicating that the connection is not direct.

Setting **dm.proxy.protects** to **0** removes the **proxy-** prefix and allows you to write a single set of protection entries that apply both to directly-connected clients as well as to those that connect via an intermediary. This is more convenient but less secure if it matters that a connection is made using an intermediary. If you use this setting, all intermediaries must be at release 2012.1 or higher.

P4Broker options

Option	Meaning
-c <i>file</i>	Specify a configuration file. Overrides P4BROKEROPTIONS setting.
-C	Output a sample configuration file, and then exit.
-d	Run as a daemon (in the background).
-f	Run as a single-threaded (non-forking) process.
-h	Print help message, and then exit.
-q	Run quietly (no startup messages).
-v	Print broker version, and then exit.

Option	Meaning
<code>-v</code> <code>subsystem</code> <code>=level</code>	<p>Set server trace options. Overrides the value of the <code>P4DEBUG</code> setting, but does <i>not</i> override the <code>debug-level</code> setting in the <code>p4broker.conf</code> file. Default is null.</p> <p>The server command trace options and their meanings are as follows.</p> <ul style="list-style-type: none"> ▪ <code>server=0</code> Disable broker command logging. ▪ <code>server=1</code> Logs broker commands to the server log file. ▪ <code>server=2</code> In addition to data logged at level <code>1</code>, logs broker command completion and basic information on CPU time used. Time elapsed is reported in seconds. On UNIX, CPU usage (system and user time) is reported in milliseconds, as per <code>getrusage()</code>. ▪ <code>server=3</code> In addition to data logged at level <code>2</code>, adds usage information for compute phases of <code>p4 sync</code> and <code>p4 flush(p4 sync -k)</code> commands. <p>For command tracing, output appears in the specified log file, showing the date, time, username, IP address, and command for each request processed by the server.</p>
<code>-Gc</code>	<p>Generate SSL credentials files for the broker: create a private key (<code>privatekey.txt</code>) and certificate file (<code>certificate.txt</code>) in <code>P4SSLDIR</code>, and then exit.</p> <p>Requires that <code>P4SSLDIR</code> be set to a directory that is owned by the user invoking the command, and that is readable only by that user. If <code>config.txt</code> is present in <code>P4SSLDIR</code>, generate a self-signed certificate with specified characteristics.</p>
<code>-Gf</code>	<p>Display the fingerprint of the broker's public key, and exit.</p> <p>Administrators can communicate this fingerprint to end users, who can then use the <code>p4 trust</code> command to determine whether or not the fingerprint (of the server to which they happen to be connecting) is accurate.</p>

Configuring the broker

P4Broker is controlled by a broker configuration file. The broker configuration file is a text file that contains rules for:

- Specifying which commands that individual users can use.
- Defining commands that are to be redirected to a specified replica server.

To generate a sample broker configuration file, issue the following command:

```
$ p4broker -C > p4broker.conf
```

You can edit the newly created `p4broker.conf` file to specify your requirements.

Format of broker configuration files

A broker configuration file contains the following sections:

- Global settings: settings that apply to all broker operations
- Alternate server definitions: the addresses and names of replica servers to which commands can be redirected in specified circumstances
- Command handler specifications: specify how individual commands should be handled. In the absence of a command handler for any given command, the Helix Broker permits the execution of that command.

Next step

"Specifying hosts" below

Specifying hosts

The broker configuration requires specification of the `target` setting, which identifies the Perforce service to which commands are to be sent, the `listen` address, which identifies the address where the broker listens for commands from Helix Server client applications, and the optional `altserver` alternate server address, which identifies a replica, proxy, or other broker connected to the Perforce service.

The host specification uses the format `protocol:host:port`, where `protocol` is the communications protocol (beginning with `ssl:` for SSL, or `tcp:` for plaintext), `host` is the name or IP address of the machine to connect to, and `port` is the number of the port on the host.

Protocol	Behavior
<code><not set></code>	<p>If the <code>net.rfc3484</code> configurable is set, allow the OS to determine which transport is used. This is applicable only if a host name (either FQDN or unqualified) is used.</p> <p>If an IPv4 literal address (e.g. <code>127.0.0.1</code>) is used, the transport is always <code>tcp4</code>, and if an IPv6 literal address (e.g. <code>:::1</code>) is used, then the transport is always <code>tcp6</code>.</p>

Protocol	Behavior
<code>tcp:</code>	Use <code>tcp4:</code> behavior, but if the address is numeric and contains two or more colons, assume <code>tcp6:</code> . If the <code>net.rfc3484</code> configurable is set, allow the OS to determine which transport is used.
<code>tcp4:</code>	Listen on/connect to an IPv4 address/port only.
<code>tcp6:</code>	Listen on/connect to an IPv6 address/port only.
<code>tcp46:</code>	Attempt to listen on/connect to an IPv4 address/port. If this fails, try IPv6.
<code>tcp64:</code>	Attempt to listen on/connect to an IPv6 address/port. If this fails, try IPv4.
<code>ssl:</code>	Use <code>ssl4:</code> behavior, but if the address is numeric and contains two or more colons, assume <code>ssl6:</code> . If the <code>net.rfc3484</code> configurable is set, allow the OS to determine which transport is used.
<code>ssl4:</code>	Listen on/connect to an IPv4 address/port only, using SSL encryption.
<code>ssl6:</code>	Listen on/connect to an IPv6 address/port only, using SSL encryption.
<code>ssl46:</code>	Attempt to listen on/connect to an IPv4 address/port. If this fails, try IPv6. After connecting, require SSL encryption.
<code>ssl64:</code>	Attempt to listen on/connect to an IPv6 address/port. If this fails, try IPv4. After connecting, require SSL encryption.

The `host` field can be the hosts' hostname or its IP address; both IPv4 and IPv6 addresses are supported. For the `listen` setting, you can use the `*` wildcard to refer to all IP addresses, but only when you are not using CIDR notation.

If you use the `*` wildcard with an IPv6 address, you must enclose the entire IPv6 address in square brackets. For example, `[2001:db8:1:2:*]` is equivalent to `[2001:db8:1:2::]/64`. Best practice is to use CIDR notation, surround IPv6 addresses with square brackets, and to avoid the `*` wildcard.

Next step

"Global settings" below

Global settings

The following settings apply to all operations you specify for the broker.

Setting	Meaning	Example
<code>target</code>	The default Helix Core Server (P4D) to which commands are sent unless overridden by other settings in the configuration file.	<code>target = [protocol:]host:port;</code>
<code>listen</code>	The address on which the Helix Broker listens for commands from Helix Server client applications.	<code>listen = [protocol:] [host:]port;</code>
<code>directory</code>	The home directory for the Helix Broker. Other paths specified in the broker configuration file must be relative to this location.	<code>directory = path;</code>
<code>logfile</code>	Path to the Helix Broker logfile.	<code>logfile = path;</code>
<code>debug-level</code>	Level of debugging output to log. Overrides the value specified by the <code>-v</code> option and <code>P4DEBUG</code> . You can specify more than one value; see example.	<code>debug-level = server=1;</code> <code>debug-level = server=1, time=1, rpl=3;</code>
<code>admin-name</code>	The name of your Helix Server Administrator. This is displayed in certain error messages.	<code>admin-name = "P4 Admin";</code>
<code>admin-email</code>	An email address where users can contact their Helix Server Administrator. This address is displayed to users when broker configuration problems occur.	<code>admin-email = admin@example.com;</code>
<code>admin-phone</code>	The telephone number of the Helix Server Administrator.	<code>admin-phone = nnnnnnn;</code>

Setting	Meaning	Example
<code>redirection</code>	<p>The redirection mode to use: <code>selective</code> or <code>pedantic</code>.</p> <p>In <code>selective</code> mode, redirection is permitted within a session until one command has been executed against the default (target) server. From then on, all commands within that session run against the default server and are not redirected.</p> <p>In <code>pedantic</code> mode, all requests for redirection are honored.</p> <p>The default mode is <code>selective</code>.</p>	<code>redirection = selective;</code>
<code>service-user</code>	<p>An optional user account by which the broker authenticates itself when communicating with a target server.</p> <p>The broker configuration does not include a setting for specifying a password as this is considered insecure. Use the <code>p4 login -u service-user -p</code> command to generate a ticket. Store the displayed ticket value in a file, and then set the <code>ticket-file</code> setting to the path of that file.</p> <p>To provide continuous operation of the broker, the <code>service-user</code> user should be included in a group that has its <code>Timeout</code> setting set to <code>unlimited</code>. The default ticket timeout is 12 hours.</p>	<code>service-user = svcbroker;</code>
<code>ticket-file</code>	An optional alternate location for <code>P4TICKETS</code> files.	<code>ticket-file = /home/p4broker/.p4tickets;</code>

Setting	Meaning	Example
<code>compress</code>	Compress connection between broker and server. Over a slow link such as a WAN, compression can increase performance. If the broker and the server are near to each other (and especially if they reside on the same physical machine), then bandwidth is not an issue, and compression should be disabled to spare CPU cycles.	<code>compress = false;</code>
<code>altserver</code>	<p>An optional alternate server to help reduce the load on the target server. The <i>name</i> assigned to the alternate server is used in command handler specifications. See "Alternate server definitions" on page 103.</p> <p>Multiple <code>altserver</code> settings may appear in the broker configuration file, one for each alternate server.</p>	<pre>altserver name { target= [protocol:]host:port };</pre> <p>Each <code>altserver</code> setting must appear on one line.</p>

Next step

["Command handler specifications" below](#)

Command handler specifications

Command handlers enable you to specify how the broker responds to different commands issued by different users from within different environments. When users run commands, the Helix Broker searches for matching command handlers and uses the first match found. If no command handler matches the user's command, the command is forwarded to the target Helix Core Server for normal processing.

The general syntax of a command handler specification is outlined in the sample `broker.conf`:

```
command: commandpattern
{
# Conditions for the command to meet (optional)
# Note that with the exception of 'flags', these are regex patterns.
  flags          = required-flags;
  args           = required-arguments;
```

```

user          = required-user;
workspace     = required-client-workspace;
prog         = required-client-program;
version      = required-version-of-client-program;

# What to do with matching commands (required)
action = pass | reject | redirect | filter | respond ;

# How to go about it
destination = altserver;           # Required for action = redirect
execute = /path/to/filter/program; # Required for action = filter
message = rejection-message;      # Required for action = reject
}

```

The *commandpattern* parameter can be a regular expression and can include the `.*` wildcard. For example, a *commandpattern* of `user.*` matches both the `p4 user` and `p4 users` commands. See ["Regular expression synopsis" on the facing page](#).

The following table describes the parameters in detail.

Parameter	Meaning
flags	A list of options that must be present on the command line of the command being handled. This feature enables you to specify different handling for the same <code>p4</code> command, depending on which options the user specifies. Note that only single character options may be specified here. Multi-character options, and options that take arguments should be handled by a filter program.
args	A list of arguments that must be present on the command line of the command being handled.
user	The name of the user who issued the command.
workspace	The Helix Server client workspace setting in effect when the command was issued.
prog	The Helix Server client application through which the user issued the command. This feature enables you to handle commands on a per-application basis.
version	The version of the Helix Server application through which the user issued the command.

Parameter	Meaning
action	Defines how the Helix Broker handles the specified commands. Valid values are: pass , reject , redirect , filter , or respond .
destination	<p>For redirected commands, the name of the replica to which the commands are redirected. The destination must be the name of a previously defined alternate (replica) server listed in the altserver setting.</p> <p>You can implement load-balancing by setting the destination to the keyword random. Commands are randomly redirected to any alternate (replica) server that you have already defined.</p> <p>You can also set destination to the address:port of the server where you want commands redirected.</p>
execute	The path to a filter program to be executed. For details about filter programs, see "Filter programs" on the next page .
message	A message to be sent to the user, typically before the command is executed; this may be used with any of the above actions.
checkauth	Authenticates the connection. If set to true , the Helix Broker checks that the user has access to the Helix Core Server before performing the action by running p4 protects -m with the user's connection. If set to false , or if not set, Helix Broker does not perform the check. If a filter program is run, the highest level permission that the user has is passed in as the maxPerm parameter. For details about filter programs, see "Filter programs" on the next page .

For example, the following command handler prevents user **joe** from invoking **p4 submit** from the **buildonly** client workspace.

```
command: submit
{
  user = joe;
  workspace = buildonly;
  action = reject;
  message = "Submit failed: Please do not submit from this workspace."
}
```

Regular expression synopsis

A regular expression, or *regex*, is a sequence of characters that forms a search pattern, for use in pattern matching with strings. The following is a short synopsis of the regex facility available in command handler specifications.

A regular expression is formed from zero or more *branches*. Branches are separated by `|`. The regex matches any string that matches at least one of the branches.

A branch is formed from zero or more *pieces*, concatenated together. A branch matches when all of its pieces match in sequence, that is, a match for the first piece, followed by a match for the second piece, etc.

A piece is an *atom* possibly followed by a *quantifier*: `*`, `+`, or `?`. An atom followed by `*` matches a sequence of 0 or more instances of the atom. An atom followed by `+` matches a sequence of 1 or more instances of the atom. An atom followed by `?` matches a sequence of 0 or 1 instances of the atom.

An atom is:

- a subordinate regular expression in parentheses - matches that subordinate regular expression
- a range (see below),
- `.` - matches any single character,
- `^` - matches the beginning of the string,
- `$` - matches the end of the string,
- a `\` followed by a single character - matches that character,
- or a single character with no other significance - matches that character.

A range is a sequence of characters enclosed in square brackets (`[]`), and normally matches any single character from the sequence. If the sequence begins with `^`, it matches any single character that is *not* in the sequence. If two characters in the sequence are separated by `-`, this is shorthand for the full list of ASCII characters between them (e.g. `[0-9]` matches any decimal digit, `[a-z]` matches any lowercase alphabetical character). To include a literal `]` in the sequence, make it the first character (following a possible `^`). To include a literal `-`, make it the first or last character.

Filter programs

When the *action* for a command handler is `filter`, the Helix Broker executes the program or script specified by the `execute` parameter and performs the action returned by the program. Filter programs enable you to enforce policies beyond the capabilities provided by the broker configuration file.

The Helix Broker invokes the filter program by passing command details to the program's standard input in the following format:

Command detail	Definition
<code>command:</code>	User command
<code>brokerListenPort:</code>	Port on which the broker is listening
<code>brokerTargetPort:</code>	Port on which the target server is listening
<code>clientPort:</code>	P4PORT setting of the client
<code>clientProg:</code>	Client application program

Command detail	Definition
clientVersion:	Version of client application program
clientProtocol:	Level of client protocol
apiProtocol:	Level of api protocol
maxLockTime:	Maximum lock time (in ms) to lock tables before aborting
maxPerm	Highest permission (if " checkauth " on page 99 is set)
maxResults:	Maximum number of rows of result data to be returned
maxScanRows:	Maximum number of rows of data scanned by a command
workspace:	Name of client workspace
user:	Name of requesting user
clientIp:	IP address of client
proxyIp:	IP address of proxy (if any)
cwd:	Client's working directory
argCount:	Number of arguments to command
Arg0:	First argument (if any)
Arg1:	Second argument (if any)
clientHost:	Hostname of the client
brokerLevel:	The internal version level of the broker.
proxyLevel:	The internal version level of the proxy (if any).

Non-printable characters in command arguments are sent to filter programs as a percent sign followed by a pair of hex characters representing the ASCII code for the non-printable character in question. For example, the tab character is encoded as `%09`.

Your filter program must read this data from STDIN before performing any additional processing, regardless of whether the script requires the data. If the filter script does not read the data from STDIN, "broken pipe" errors can occur, and the broker rejects the user's command.

Your filter program must respond to the Broker on standard output (stdout) with data in one of the four following formats:

```
action: PASS
message: a message for the user (optional)
```

```
action: REJECT
message: a message for the user (required)
```

```
action: REDIRECT
altserver: (an alternate server name)
message: a message for the user (optional)
```

```
action: RESPOND
message: a message for the user (required)
```

```
action: CONTINUE
```

Note

The values for the **action** are case-sensitive.

The **action** keyword is always required and tells the Broker how to respond to the user's request. The available **actions** are:

Action	Definition
PASS	Run the user's command unchanged. A message for the user is optional.
REJECT	Reject the user's command; return an error message. A message for the user is required.
REDIRECT	<p>Redirect the command to a different (alternate) replica server. An altserver is required. See "Configuring alternate servers to work with central authorization servers" on the facing page for details. A message for the user is optional.</p> <p>To implement this action, the broker makes a new connection to the alternate server and routes all messages from the client to the alternate server rather than to the original server. This is unlike HTTP redirection where the client is requested to make its own direct connection to an alternate web server.</p>
RESPOND	Do not run the command; return an informational message. A message for the user is required.
CONTINUE	<p>Defer to the next command handler matching a given command.</p> <p>For information on using multiple handlers, see the Support Knowledgebase article, "How the Broker can process multiple command handlers".</p>

If the filter program returns any response other than something complying with the four message formats above, the user's command is rejected. If errors occur during the execution of your filter script code cause the broker to reject the user's command, the broker returns an error message.

Broker filter programs have difficulty handling multi-line message responses. You must use syntax like the following to have new lines be interpreted correctly when sent from the broker:

```
message="\line 1\nline 3\nline f\n"
```

That is, the string must be quoted twice.

Next step

"Alternate server definitions" below

Alternate server definitions

The Helix Broker can direct user requests to an alternate server to reduce the load on the target server. These alternate servers must be replicas (or brokers, or proxies) connected to the intended target server.

To set up and configure a replica server, see "[Helix Server replication](#)" on page 25. The broker works with both metadata-only replicas and with replicas that have access to both metadata and versioned files.

There is no limit to the number of alternate replica servers you can define in a broker configuration file.

The syntax for specifying an alternate server is as follows:

```
altserver name { target=[protocol:]host:port }
```

The name assigned to the alternate server is used in command handler specifications. See "[Command handler specifications](#)" on page 97.

Configuring alternate servers to work with central authorization servers

Alternate servers require users to authenticate themselves when they run commands. For this reason, the Helix Broker must be used in conjunction with a central authorization server (**P4AUTH**) and Helix Servers at version 2007.2 or later. For more information about setting up a central authorization server, see "[Configuring centralized authorization and changelist servers](#)" on page 20.

When used with a central authorization server, a single **p4 login** request can create a ticket that is valid for the user across all servers in the Helix Broker's configuration, enabling the user to log in once. The Helix Broker assumes that a ticket granted by the target server is valid across all alternate servers.

If the target server in the broker configuration file is a central authorization server, the value assigned to the **target** parameter must precisely match the setting of **P4AUTH** on the alternate server machine(s). Similarly, if an alternate sever defined in the broker configuration file is used as the central authorization server, the value assigned to the **target** parameter for the alternate server must match the setting of **P4AUTH** on the other server machine(s).

Using the broker as a load-balancing router

Previous sections described how you can use the broker to direct specific commands to specific servers. You can also configure the broker to act as a load-balancing router. When you configure a broker to act as a router, Helix Server builds a **db.routing** table that is processed by the router to determine which server an incoming command should be routed to. (The **db.routing** table provides a mapping of clients and users to their respective servers. To reset the **db.routing** table, remove the **db.routing** file.)

This section explains how you configure the broker to act as a router, and it describes routing policy and behavior.

Configuring the broker as a router	104
Routing policy and behavior	104

Configuring the broker as a router

To configure the broker as a router, add the `router` statement to the top level of the broker configuration. The target server of the broker-router should be a commit or master server.

```
target      = commitserv.example.com:1666;
listen     = 1667;
directory  = /p4/broker;
logfile    = broker.log;
debug-level = server=1;
admin-name = "Perforce Admins";
admin-phone = 999/911;
admin-email = perforce-admins@example.com;
router;
```

You must then include `altserver` statements to specify the edge servers of the commit server that is the target server of the broker-router.

```
altserver: edgeserv1
{
    target = edgeserv1.example.com:1669;
}
```

If you are using the broker to route messages for a commit-edge architecture, you must list all existing edge servers as `altserver`s.

Next step

"Routing policy and behavior" below

Routing policy and behavior

When a command arrives at the broker, the broker looks in its `db.routing` table to determine where the command should be routed. The routing logic attempts to bind a user to a server where they already have clients. You can modify the routing choice on the `p4` command line using the following argument to override routing for that command.

```
-Zroute=serverID
```

Routing logic uses a default destination server, chosen at random, if a client and user have no binding to an existing edge server. That is, requests are routed to an existing altserver that is randomly chosen unless a specific destination is given.

- To route requests to the commit server, use the destination form as follows:

```
target      = commitserv.example.com:1666;
listen      = 1667;
directory   = /p4/broker;
logfile     = broker.log;
debug-level = server=1;
admin-name  = "Perforce Admins";
admin-phone = 999/911;
admin-email = perforce-admins@example.com;

router;
destination target;
```

- To cause new users to be bound to a new edge server rather than being assigned to existing edge servers, use a destination form like the following:

```
target      = commitserv.example.com:1666;
listen      = 1667;
directory   = /p4/broker;
logfile     = broker.log;
debug-level = server=1;
admin-name  = "Perforce Admins";
admin-phone = 999/911;
admin-email = perforce-admins@example.com;

router;
destination = "myNewEdge";
```

- To force a command to be routed to the commit server, use an `action = redirect` rule with a `destination target` statement; for example:

```
command: regex pattern
{
  action=redirect;
  destination target;
}
```

Note

You need to remove the `db.routing` file when you move clients to a different workspace or edge server.

Helix Proxy

This topic assumes you have read the "Introduction to federated services" on page 9.

To improve performance obtained by multiple Helix Server users accessing a shared Helix Server repository across a WAN,

1. Configure P4P on the side of the network close to the users.
2. Configure the users to access the service through P4P.
3. Configure P4P to access the master Perforce service.

System requirements	107
Installing P4P	108
UNIX	108
Windows	108
Running P4P	108
Running P4P as a Windows service	108
P4P options	109
Administering P4P	111
No backups required	112
Stopping P4P	112
Upgrading P4P	112
Enabling SSL support	112
Defending from man-in-the-middle attacks	112
Localizing P4P	113
Managing disk space consumption	113
Determining if your Helix Server applications are using the proxy	113
P4P and protections	114
Determining if specific files are being delivered from the proxy	115
Case-sensitivity issues and the proxy	116
Maximizing performance improvement	116
Reducing server CPU usage by disabling file compression	116
Network topologies versus P4P	117
Preloading the cache directory for optimal initial performance	117
Distributing disk space consumption	118

System requirements

To use Helix Proxy, you must have:

- Helix Server release 2002.2 or later (2012.1 or later to use SSL)
- Sufficient disk space on the proxy host to store a cache of file revisions

Installing P4P

In addition to the basic steps described next, see:

- "Enabling SSL support" on page 112
- "Defending from man-in-the-middle attacks" on page 112

UNIX	108
Windows	108

UNIX

To install P4P on UNIX or Linux, do the following:

1. Download the **p4p** executable to the machine on which you want to run the proxy.
2. Select a directory on this machine (**P4PCACHE**) in which to cache file revisions.
3. Select a port (**P4PORT**) on which **p4p** will listen for requests from Helix Server applications.
4. Select the target Helix Server (**P4TARGET**) for which this proxy will cache.

Windows

Install P4P from the Windows installer's custom/administrator installation dialog.

Running P4P

To run Helix Proxy, invoke the **p4p** executable, configuring it with environment variables or command-line options. Options you specify on the command line override environment variable settings.

For example, the following command line starts a proxy that communicates with a central Helix Server located on a host named **central**, listening on port 1666.

```
$ p4p -p tcp64:[::]:1999 -t central:1666 -r /var/proxyroot
```

To use the proxy, Helix Server applications connect to P4P on port 1999 on the machine where the proxy runs. The proxy listens on both the IPv6 and IPv4 transports. P4P file revisions are stored under a directory named **/var/proxyroot**.

P4P supports connectivity over IPv6 networks as well as IPv4. See the *Helix Core Server Administrator Guide: Fundamentals* for more information.

Running P4P as a Windows service

To run P4P as a Windows service, either install P4P from the Windows installer, or specify the **-s** option when you invoke **p4p.exe**, or rename the P4P executable to **p4ps.exe**.

To pass parameters to the P4Proxy service, set the **P4POPTIONS** registry variable using the **p4 set** command. For example, if you normally run the Proxy with the command:

```
C:\> p4p -p 1999 -t ssl:mainserver:1666
```

You can set the **P4POPTIONS** variable for a Windows service named **Helix Proxy** by setting the service parameters as follows:

```
C:\> p4 set -S "Perforce Proxy" P4POPTIONS="-p 1999 -t
ssl:mainserver:1666"
```

When the "**Helix Proxy**" service starts, P4P listens for plaintext connections on port 1999 and communicates with the Helix Core Server via SSL at **ssl:mainserver:1666**.

P4P options

The following command-line options specific to the proxy are supported.

Proxy options:

Option	Meaning
-d	Run as daemon - fork first, then run (UNIX only).
-f	Do not fork - run as a single-threaded server (UNIX only).
-i	Run for inetd (socket on stdin/stdout - UNIX only).
-q	Run quietly; suppress startup messages.
-c	Do not compress data stream between the Helix Server to P4P. (This option reduces CPU load on the central server at the expense of slightly higher bandwidth consumption.)
-s	Run as a Windows service (Windows only). Running p4p.exe -s is equivalent to invoking p4ps.exe .
-S	Disable cache fault coordination. The proxy maintains a table of concurrent sync operations, called pdb.lbr , to avoid multiple transfers of the same file. This mechanism prevents unnecessary network traffic, but can impart some delay to operations until the file transfer is complete. When -S is used, cache fault coordination is disabled, allowing multiple transfers of files to occur. The proxy then decides whether to transfer a file based solely on its checksum. This may increase the burden on the network, while potentially providing speedier completion for sync operations.

General options:

Option	Meaning
-h or -?	Display a help message.
-v	Display the version of the Helix Proxy.
-r <i>root</i>	Specify the directory where revisions are cached. Default is P4PCACHE , or the directory from which p4p is started if P4PCACHE is not set.
-L <i>logfile</i>	Specify the location of the log file. Default is P4LOG , or the directory from which p4p is started if P4LOG is not set.
-p <i>port</i>	Specify the port on which P4P will listen for requests from Helix Server applications. Default is P4PORT , or 1666 if P4PORT is not set.
-t <i>port</i>	Specify the port of the target Helix Server (that is, the Helix Server for which P4P acts as a proxy). Default is P4TARGET or perforce:1666 if P4TARGET is not set.
-e <i>size</i>	Cache only those files that are larger than <i>size</i> bytes. Default is P4PFSIZE , or zero (cache all files) if P4PFSIZE is not set.
-u <i>serviceuser</i>	For proxy servers, authenticate as the specified serviceuser when communicating with the central server. The service user must have a valid ticket before the proxy will work.
-v <i>level</i>	Specifies server trace level. Debug messages are stored in the proxy server's log file. Debug messages from p4p are not passed through to p4d , and debug messages from p4d are not passed through to instances of p4p . Default is P4DEBUG , or none if P4DEBUG is not set.

Certificate-handling options:

Option	Meaning
-Gc	Generate SSL credentials files for the proxy: create a private key (privatekey.txt) and certificate file (certificate.txt) in P4SSLDIR , and then exit. Requires that P4SSLDIR be set to a directory that is owned by the user invoking the command, and that is readable only by that user. If config.txt is present in P4SSLDIR , generate a self-signed certificate with specified characteristics.
-Gf	Display the fingerprint of the proxy's public key, and exit. Administrators can communicate this fingerprint to end users, who can then use the p4 trust command to determine whether or not the fingerprint (of the server to which they happen to be connecting) is accurate.

Proxy monitoring options:

Option	Meaning
<code>-l</code>	List pending archive transfers
<code>-l -s</code>	List pending archive transfers, summarized
<code>-v lbr.stat.interval=n</code>	Set the file status interval, in seconds. If not set, defaults to 10 seconds.
<code>-v proxy.monitor.level=n</code>	<p>0: (default) Monitoring disabled</p> <p>1: Proxy monitors file transfers only</p> <p>2: Proxy monitors all operations</p> <p>3: Proxy monitors all traffic for all operations</p>
<code>-v proxy.monitor.interval=n</code>	Proxy monitoring interval, in seconds. If not set, defaults to 10 seconds.
<code>-m1</code> <code>-m2</code> <code>-m3</code>	<p>Show currently-active connections and their status.</p> <p>Requires <code>proxy.monitor.level</code> set equal to or greater than 1. The optional argument specifies the level of detail: <code>-m1</code>, <code>-m2</code>, or <code>-m3</code> show increasing levels of detail corresponding to the <code>proxy.monitor.level</code> setting.</p>

Proxy archive cache options:

Option	Meaning
<code>-v lbr.proxy.case=n</code>	<p>1: (default) Proxy folds case; all files with the same name are assumed to be the same file, regardless of case.</p> <p>2: Proxy folds case if, and only if, the upstream server is case-insensitive (that is, if the upstream server is on Windows)</p> <p>3: Proxy never folds case.</p>

Administering P4P

The following sections describe the tasks involved in administering a proxy.

No backups required	112
Stopping P4P	112
Upgrading P4P	112
Enabling SSL support	112
Defending from man-in-the-middle attacks	112
Localizing P4P	113

Managing disk space consumption	113
Determining if your Helix Server applications are using the proxy	113
P4P and protections	114
Determining if specific files are being delivered from the proxy	115
Case-sensitivity issues and the proxy	116

No backups required

You never need to back up the P4P cache directory.

If necessary, P4P reconstructs the cache based on Helix Server metadata.

Stopping P4P

P4P is effectively stateless; to stop P4P under UNIX, **kill** the **p4p** process with **SIGTERM** or **SIGKILL**. Under Windows, click **End Process** in the **Task Manager**.

Upgrading P4P

After you have replaced the **p4p** executable with the upgraded version, you must also remove the **pdb.lbr** and **pdb.monitor** files (if they exist) from the proxy root before you restart the upgraded proxy.

Enabling SSL support

To encrypt the connection between a Helix Proxy and its end users, your proxy must have a valid private key and certificate pair in the directory specified by its **P4SSLDIR** environment variable. Certificate and key generation and management for the proxy works the same as it does for the Helix Core Server. See "Enabling SSL support" on page 36. The users' Helix Server applications must be configured to trust the fingerprint of the proxy.

To encrypt the connection between a Helix Proxy and its upstream Perforce service, your proxy installation must be configured to trust the fingerprint of the upstream Perforce service. That is, the user that runs **p4p** (typically a service user) must create a **P4TRUST** file (using **p4 trust**) that recognizes the fingerprint of the upstream Perforce service.

See the Knowledge Base article, "Enabling SSL Support for the Server/Broker/Proxy".

Defending from man-in-the-middle attacks

You can use the **net.mimcheck** configurable to enable checks for possible interception or modification of data. These settings are pertinent for proxy administration:

- A value of 3 checks connections from clients, proxies, and brokers for TCP forwarding.
- A value of 5 requires that proxies, brokers, and all Helix Server intermediate servers have valid logged-in service users associated with them. This allows administrators to prevent unauthorized proxies and services from being used.

You must restart the server after changing the value of this configurable. See `net.mimcheck`.

Localizing P4P

If your Helix Server has localized error messages (see "Localizing server error messages" in *Helix Core Server Administrator Guide: Fundamentals*), you can localize your proxy's error message output by shutting down the proxy, copying the server's `db.message` file into the proxy root, and restarting the proxy.

Managing disk space consumption

P4P caches file revisions in its cache directory. These revisions accumulate until you delete them. P4P does not delete its cached files or otherwise manage its consumption of disk space.

Warning

If you do not delete cached files, you will eventually run out of disk space. To recover disk space, remove files under the proxy's root.

You do not need to stop the proxy to delete its cached files or the `pdb.lbr` file.

If you delete files from the cache without stopping the proxy, you must also delete the `pdb.lbr` file at the proxy's root directory. (The proxy uses the `pdb.lbr` file to keep track of which files are scheduled for transfer, so that if multiple users simultaneously request the same file, only one copy of the file is transferred.)

Determining if your Helix Server applications are using the proxy

If your Helix Server application is using the proxy, the proxy's version information appears in the output of `p4 info`.

For example, if a Perforce service is hosted at `ssl:central:1666` and you direct your Helix Server application to a Helix Proxy hosted at `outpost:1999`, the output of `p4 info` resembles the following:

```
$ export P4PORT=tcp:outpost:1999
$ p4 info
User name: p4adm
```

```

Client name: admin-temp
Client host: remotesite22
Client root: /home/p4adm/tmp
Current directory: /home/p4adm/tmp
Client address: 192.168.0.123
Server address: central:1666
Server root: /usr/depot/p4d
Server date: 2012/03/28 15:03:05 -0700 PDT
Server uptime: 752:41:23
Server version: P4D/FREEBSD4/2012.1/406375 (2012/01/25)
Server encryption: encrypted
Proxy version: P4P/SOLARIS26/2012.1/406884 (2012/01/25)
Server license: P4 Admin <p4adm> 20 users (expires 2013/01/01)
Server license-ip: 10.0.0.2
Case handling: sensitive

```

P4P and protections

To apply the IP address of a Helix Proxy user's workstation against the protections table, prepend the string `proxy-` to the workstation's IP address.

Important

Before you prepend the string `proxy-` to the workstation's IP address, make sure that a broker or proxy is in place.

For instance, consider an organization with a remote development site with workstations on a subnet of `192.168.10.0/24`. The organization also has a central office where local development takes place; the central office exists on the `10.0.0.0/8` subnet. A Perforce service resides in the `10.0.0.0/8` subnet, and a Helix Proxy resides in the `192.168.10.0/24` subnet. Users at the remote site belong to the group `remotedev`, and occasionally visit the central office. Each subnet also has a corresponding set of IPv6 addresses.

To ensure that members of the `remotedev` group use the proxy while working at the remote site, but do not use the proxy when visiting the local site, add the following lines to your protections table:

```

list    group    remotedev    192.168.10.0/24    -//...
list    group    remotedev    [2001:db8:16:81::]/48    -//...
write   group    remotedev    proxy-192.168.10.0/24    //...
write   group    remotedev    proxy-[2001:db8:16:81::]/48    //...
list    group    remotedev    proxy-10.0.0.0/8    -//...

```

```
list    group    remotede    proxy-[2001:db8:1008::]/32    -//...
write   group    remotede    10.0.0.0/8                      //...
write   group    remotede    proxy-[2001:db8:1008::]/32     //...
```

The first line denies **list** access to all users in the **remotede** group if they attempt to access Helix Server without using the proxy from their workstations in the **192.168.10.0/24** subnet. The second line denies access in identical fashion when access is attempted from the IPv6 **[2001:db8:16:81::]/48** subnet.

The third line grants **write** access to all users in the **remotede** group if they are using a Helix Proxy server and are working from the **192.168.10.0/24** subnet. Users of workstations at the remote site must use the proxy. (The proxy server itself does not have to be in this subnet, for example, it could be at **192.168.20.0**.) The fourth line grants access in identical fashion when access is attempted from the IPv6 **[2001:db8:16:81::]/48** subnet.

Similarly, the fifth and sixth lines deny **list** access to **remotede** users when they attempt to use the proxy from workstations on the central office's subnets (**10.0.0.0/8** and **[2001:db8:1008::]/32**). The seventh and eighth lines grant write access to **remotede** users who access the Helix Server directly from workstations on the central office's subnets. When visiting the local site, users from the **remotede** group must access the Helix Server directly.

When the Perforce service evaluates protections table entries, the **dm.proxy.protects** configurable is also evaluated.

dm.proxy.protects defaults to **1**, which causes the **proxy-** prefix to be prepended to all client host addresses that connect via an intermediary (proxy, broker, replica, or edge server), indicating that the connection is not direct.

Setting **dm.proxy.protects** to **0** removes the **proxy-** prefix and allows you to write a single set of protection entries that apply both to directly-connected clients as well as to those that connect via an intermediary. This is more convenient but less secure if it matters that a connection is made using an intermediary. If you use this setting, all intermediaries must be at release 2012.1 or higher.

Determining if specific files are being delivered from the proxy

Use the **-Zproxyverbose** option with **p4** to display messages indicating whether file revisions are coming from the proxy (**p4p**) or the central server (**p4d**). For example:

```
$ p4 -Zproxyverbose sync noncached.txt
//depot/main/noncached.txt - refreshing /home/p4adm/tmp/noncached.txt
$ p4 -Zproxyverbose sync cached.txt
//depot/main/cached.txt - refreshing /home/p4adm/tmp/cached.txt
File /home/p4adm/tmp/cached.txt delivered from proxy server
```

Case-sensitivity issues and the proxy

If you are running the proxy on a case-sensitive platform such as UNIX, and your users are submitting files from case-insensitive platforms (such as Windows), the default behavior of the proxy is to fold case; that is, `FILE.TXT` can overwrite `File.txt` or `file.txt`.

In the case of text files and source code, the performance impact of this behavior is negligible. If, however, you are dealing with large binaries such as `.ISO` images or `.VOB` video objects, there can be performance issues associated with this behavior.)

<code>lbr.proxy.case</code>	Behavior
<code>lbr.proxy.case=1</code> (default)	Proxy folds case; all files with the same name are assumed to be the same file, regardless of case.
<code>lbr.proxy.case=2</code>	Proxy folds case if, and only if, the upstream server is case-insensitive (that is, if the upstream server is on Windows)
<code>lbr.proxy.case=3</code>	Proxy never folds case.

After any change to `lbr.proxy.case`, you must clear the cache before restarting the proxy.

Maximizing performance improvement

In addition to the topics in this chapter, see the Support Knowledgebase article on tuning tips for "Proxy Performance", including how to minimize the syncing of small files.

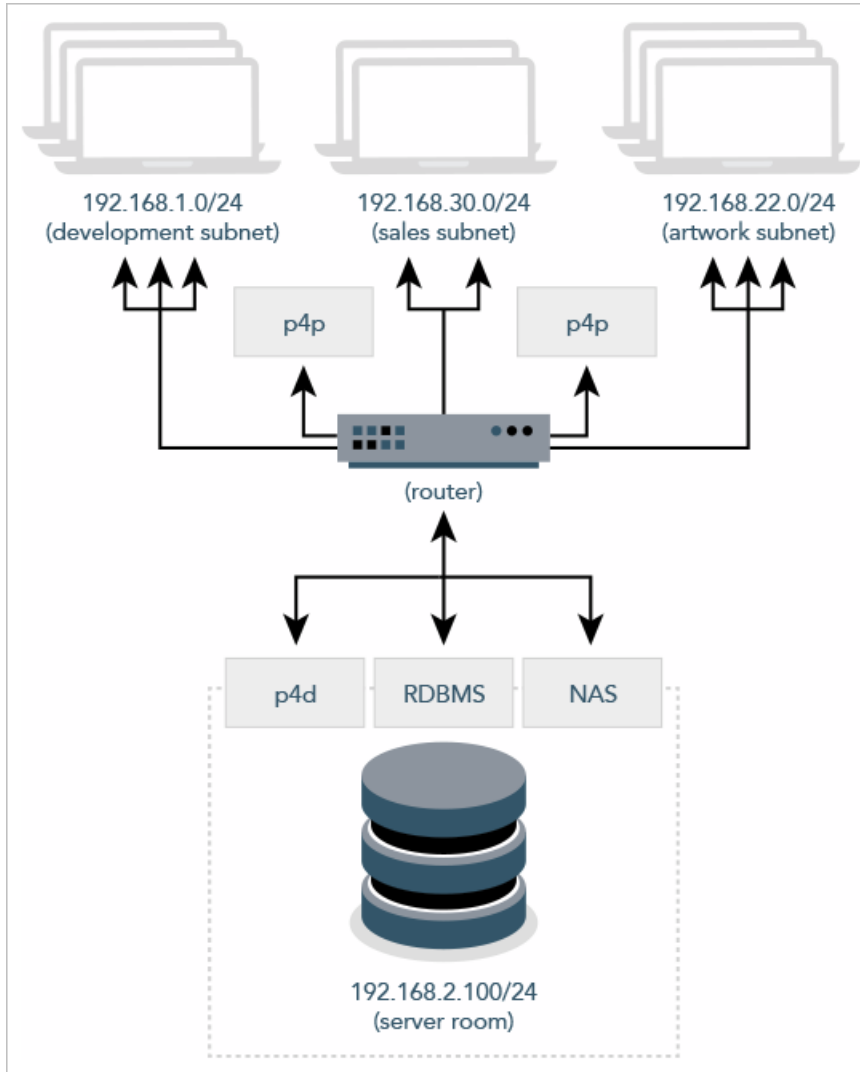

Reducing server CPU usage by disabling file compression	116
Network topologies versus P4P	117
Preloading the cache directory for optimal initial performance	117
Distributing disk space consumption	118

Reducing server CPU usage by disabling file compression

By default, P4P compresses communication between itself and the Helix Server versioning service, imposing additional overhead on the service. To disable compression, specify the `-c` option when you invoke `p4p`. This option is particularly effective if you have excess network and disk capacity and are storing large numbers of binary file revisions in the depot, because the proxy (rather than the upstream versioning service) decompresses the binary files from its cache before sending them to Helix Server users.

Network topologies versus P4P

If network bandwidth on the subnet with the Perforce service is nearly saturated, deploy the proxies on the other side of a router so that the traffic from end users to the proxy is isolated to a subnet separate from the subnet containing the Perforce service. You might split the subnet into multiple subnets and deploy a proxy in each resulting subnet:

Preloading the cache directory for optimal initial performance

Helix Proxy stores file revisions only when one of its users submits a new revision to the depot or requests an existing revision from the depot. That is, file revisions are not prefetched. Performance gains from P4P occur only after file revisions are cached.

After starting P4P, you can prefetch the cache directory by creating a dedicated client workspace and syncing it to the head revision. All other users who subsequently connect to the proxy immediately obtain the performance improvements provided by P4P. For example, a development site located in Asia with a P4P server targeting a Helix Server in North America can preload its cache directory by using an automated job that runs a `p4 sync` against the entire Helix Server depot after most work at the North American site has been completed, but before its own developers arrive for work.

By default, `p4 sync` writes files to the client workspace. If you have a dedicated client workspace that you use to prefetch files for the proxy, however, this step is redundant. If this machine has slower I/O performance than the machine running the Helix Proxy, it can also be time-consuming.

To preload the proxy's cache without the redundant step of also writing the files to the client workspace, use the `-Zproxyload` option when syncing. For example:

```
$ export P4CLIENT=prefetch
$ p4 sync //depot/main/written.txt
//depot/main/written.txt - refreshing /home/prefetch/main/written.txt
$ p4 -Zproxyload sync //depot/main/nonwritten.txt
//depot/main/nonwritten.txt - file(s) up-to-date.
```

Both files are now cached, but `nonwritten.txt` is never written to the the `prefetch` client workspace. When prefetching the entire depot, the time savings can be considerable.

Distributing disk space consumption

P4P stores revisions as if there were only one depot tree. If this approach stores too much file data onto one filesystem, you can use symbolic links to spread the revisions across multiple filesystems.

For instance, if the P4P cache root is `/disk1/proxy`, and the Helix Server it supports has two depots named `//depot` and `//released`, you can split data across disks, storing `//depot` on `disk1` and `//released` on `disk2` as follows:

```
$ mkdir /disk2/proxy/released
$ cd /disk1/proxy
$ ln -s /disk2/proxy/released released
```

The symbolic link means that when P4P attempts to cache files in the `//released` depot to `/disk1/proxy/released`, the files are stored on `/disk2/proxy/released`.

Helix Core Server (p4d) Reference

Start the Perforce service or perform checkpoint/journaling (system administration) tasks.

Syntax

```
p4d [ options ]  
p4d.exe [ options ]  
p4s.exe [ options ]  
p4d -j? [ -z | -Z ] [ args ... ]
```

Description

The first three forms of the command invoke the background process that manages the Helix Server versioning service.

The fourth form is for system administration tasks involving checkpointing and journaling.

On UNIX and Mac OS X, the executable is **p4d**.

On Windows, the executable is **p4d.exe** (running as a server) or **p4s.exe** (running as a service).

Exit Status

After successful startup, **p4d** does not normally exit. It merely outputs the following startup message:

```
Perforce server starting...
```

and runs in the background.

On failed startup, **p4d** returns a nonzero error code.

Also, if invoked with any of the **-j** checkpointing or journaling options, **p4d** exits with a nonzero error code if any error occurs.

Options

Server options	Meaning
-d	Run as a daemon (in the background).
-f	Run as a single-threaded (non-forking) process.

Server options	Meaning
<code>-i</code>	Run from <code>inetd</code> on UNIX.
<code>-q</code>	Run quietly (no startup messages).
<code>--pid-file[=<i>file</i>]</code>	Write the PID of the server to a file named <code>server.pid</code> in the directory specified by <code>P4ROOT</code> , or write the PID to the file specified by <code>file</code> . This makes it easier to identify a server instance among many. The <code>file</code> parameter can be a complete path specification. The file does not have to reside in <code>P4ROOT</code> .
<code>--daemonsafe</code>	Is like <code>-d</code> and forks the <code>p4d</code> into the background, but also closes the stdio (standard input output) files.
<code>-xi</code>	Irreversibly reconfigure the Helix Core Server (and its metadata) to operate in Unicode mode. Do not use this option unless you know you require Unicode mode. For details, see the Release Notes and the Internationalization Notes .
<code>-xu</code>	Run database upgrades and exit. Upgrades must be run manually unless the server is a DVCS personal server, which runs upgrade steps automatically.
<code>-xv</code>	Run low-level database validation and quit.
<code>-xvU</code>	Run fast verification. Do not lock database tables, and verify only that the unlock count for each table is zero.
<code>-xD [<i>serverID</i>]</code>	Display (or set) the server's <code>serverID</code> (stored in the <code>server.id</code> file) and exit.

General options	Meaning
<code>-h, -?</code>	Print help message.
<code>-V</code>	Print version number.
<code>-A <i>auditlog</i></code>	Specify an audit log file. Overrides <code>P4AUDIT</code> setting. Default is null.

General options	Meaning
<code>-Id description</code>	A server description for use with <code>p4 server</code> . Overrides <code>P4DESCRIPTION</code> setting.
<code>-In name</code>	A server name for use with <code>p4 configure</code> . Overrides <code>P4NAME</code> setting.
<code>-J journal</code>	Specify a journal file. Overrides <code>P4JOURNAL</code> setting. Default is <code>journal</code> . (Use <code>-J off</code> to disable journaling.)
<code>-L log</code>	Specify a log file. Overrides <code>P4LOG</code> setting. Default is <code>STDERR</code> .
<code>-p port</code>	Specify a port to listen to. Overrides <code>P4PORT</code> . Default <code>1666</code> .
<code>-r root</code>	Specify the server root directory. Overrides <code>P4ROOT</code> . Default is current working directory.
<code>-v subsystem=level</code>	Set trace options. Overrides value <code>P4DEBUG</code> setting. Default is null.
<code>-C1</code>	Force the service to operate in case-insensitive mode on a normally case-sensitive platform.
<code>--pid-file [name]</code>	Write the server's PID to the specified file. Default name for the file is <code>server.pid</code> .

Checkpointing options	Meaning
<code>-c command</code>	Lock database tables, run <code>command</code> , unlock the tables, and exit.
<code>-jc [prefix]</code>	Journal-create; create checkpoint and <code>.md5</code> file, and save/truncate journal. In this case, your checkpoint and journal files are named <code>prefix.ckp.n</code> and <code>prefix.jnl.n</code> respectively, where <code>prefix</code> is as specified on the command line and <code>n</code> is a sequence number. If no <code>prefix</code> is specified, the default filenames <code>checkpoint.n</code> and <code>journal.n</code> are used. You can store checkpoints and journals in the directory of your choice by specifying the directory as part of the prefix.
<div style="background-color: #fff9e6; padding: 5px;"> <p>Warning If you use this option, it must be the last option on the command line.</p> </div>	
<code>-jd file</code>	Journal-checkpoint; create checkpoint and <code>.md5</code> file without saving/truncating journal.
<code>-jj [prefix]</code>	Journal-only; save and truncate journal without checkpointing.

Checkpointing options	Meaning
<code>-jr file</code>	Journal-restore; restore metadata from a checkpoint and/or journal file. If you specify the <code>-r \$P4ROOT</code> option on the command line, the <code>-r</code> option must precede the <code>-jr</code> option.
<code>-jv file</code>	Verify the integrity of the checkpoint or journal specified by <i>file</i> as follows: <ul style="list-style-type: none"> ■ Can the checkpoint or journal be read from start to finish? ■ If it is zipped, can it be successfully unzipped? ■ If it has an MD5 file with its MD5, does it match? ■ Does it have the expected header and trailer? <p>This command does not replay the journal.</p> <p>Use the <code>-z</code> option with the <code>-jv</code> option to verify the integrity of compressed journals or compressed checkpoints.</p>
<code>-z</code>	Compress (in <code>gzip</code> format) checkpoints and journals. When you use this option with the <code>-jd</code> option, Helix Server automatically adds the <code>.gz</code> extension to the checkpoint file. So, the command: <code>p4d -jd -z myCheckpoint</code> creates two files: <code>myCheckpoint.gz</code> and <code>myCheckpoint.md5</code> .
<code>-Z</code>	Compress (in <code>gzip</code> format) checkpoint, but leave journal uncompressed for use by replica servers. That is, it applies to <code>-jc</code> , not <code>-jd</code> .
Journal restore options	Meaning
<code>-jrc file</code>	Journal-restore with integrity-checking. Because this option locks the database, this option is intended only for use by replica servers started with the <code>p4 replicate</code> command.
<code>-jrF file</code>	Allow replaying a checkpoint over an existing database. (Bypass the check done by the <code>-jr</code> option to see if a checkpoint is being replayed into an existing database directory by mistake.)

Journal restore options	Meaning
<code>-b <i>bunch</i> -jr <i>file</i></code>	Read <i>bunch</i> lines of journal records, sorting and removing duplicates before updating the database. The default is 5000 , but can be set to 1 to force serial processing. This combination of options is intended for use with replica servers started with the <code>p4 replicate</code> command.
<code>-f -jr <i>file</i></code>	Ignore failures to delete records. This meaning of <code>-f</code> applies only when <code>-jr</code> is present. This combination of options is intended for use with replica servers started with the <code>p4 replicate</code> command. By default, journal restoration halts if record deletion fails. As with all journal-restore commands, if you specify the <code>-r \$P4ROOT</code> option on the command line, the <code>-r</code> option must precede the <code>-jr</code> option.
<code>-m -jr <i>file</i></code>	Schedule new revisions for replica network transfer. Required only in environments that use <code>p4 pull -u</code> for archived files, but <code>p4 replicate</code> for metadata. Not required in replicated environments based solely on <code>p4 pull</code> .
<code>-s -jr <i>file</i></code>	Record restored journal records into regular journal, so that the records can be propagated from the server's journal to any replicas downstream of the server. This combination of options is intended for use in conjunction with Perforce Support .

Replication and multi-server options	Meaning
<code>-a <i>host:port</i></code>	In multi-server environments, specify an authentication server for licensing and protections data. Overrides <code>P4AUTH</code> setting. Default is null.
<code>-g <i>host:port</i></code>	In multi-server environments, specify a changelist server from which to obtain changelist numbers. Overrides <code>P4CHANGE</code> setting. Default is null.
<code>-t <i>host:port</i></code>	For replicas, specify the target (master) server from which to pull data. Overrides <code>P4TARGET</code> setting. Default is null.

Replication and multi-server options	Meaning
<code>-u <i>serviceuser</i></code>	For replicas, authenticate as the specified <i>serviceuser</i> when communicating with the master. The service user must have a valid ticket before replica operations will succeed.
Journal dump/restore filtering	Meaning
<code>-jd <i>file</i> <i>db.table</i></code>	Dump <i>db.table</i> by creating a checkpoint <i>file</i> that contains only the data stored in <i>db.table</i> . This command can also be used with non-jourealed tables.
<code>-k <i>db.table1</i>, <i>db.table2</i>,... - jd <i>file</i></code>	Dump a set of named tables to a single dump <i>file</i> .
<code>-K <i>db.table1</i>, <i>db.table2</i>,... - jd <i>file</i></code>	Dump all tables except the named tables to the dump <i>file</i> .
<code>-P <i>serverid</i> - jd <i>file</i></code>	Specify filter patterns for <code>p4d -jd</code> by specifying a <i>serverid</i> from which to read filters (see <code>p4 help server</code> , or use the older syntax described in <code>p4 help export</code>). This option is useful for seeding a filtered replica.
<code>-k <i>db.table1</i>, <i>db.table2</i>,... - jr <i>file</i></code>	Restore from <i>file</i> , including only journal records for the tables named in the list specified by the <code>-k</code> option.

Journal dump/restore filtering	Meaning
<code>-K db.table1,db.table2,... -jr file</code>	Restore from <i>file</i> , excluding all journal records for the tables named in the list specified by the <code>-K</code> option.
Certificate Handling	Meaning
<code>-Gc</code>	<p>Generate SSL credentials files for the server: create a private key and certificate file in <code>P4SSLDIR</code>, and then exit.</p> <p>Requires that <code>P4SSLDIR</code> be set to a directory that is owned by the user invoking the command, and that is readable only by that user. If <code>config.txt</code> is present in <code>P4SSLDIR</code>, generate a self-signed certificate with specified characteristics.</p>
<code>-Gf</code>	<p>Display the fingerprint of the server's public key, and exit.</p> <p>Administrators can communicate this fingerprint to end users, who can then use the <code>p4 trust</code> command to determine whether or not the fingerprint (of the server to which they happen to be connecting) is accurate.</p>
Configuration options	Meaning
<code>-cshow</code>	Display the contents of <code>db.config</code> without starting the service. (That is, run <code>p4 configure show allservers</code> , but without a running service.)
<code>-cset server#var=val</code>	<p>Set a Helix Server configurable without starting the service, optionally specifying the server for which the configurable is to apply. For example,</p> <pre>p4d -r . "-cset replica#P4JOURNAL=off"</pre> <pre>p4d -r . "-cset replica#P4JOURNAL=off replica#server=3"</pre> <p>It is best to include the entire <code>variable=value</code> expression in quotation marks.</p>
<code>-cunset server#var</code>	Unset the specified configurable.

Usage Notes

- On all systems, journaling is enabled by default. If `P4JOURNAL` is unset when `p4d` starts, the default location for the journal is `$P4ROOT`. If you want to manually disable journaling, you must explicitly set `P4JOURNAL` to `off`.
- Take checkpoints and truncate the journal often, preferably as part of your nightly backup process.
- Checkpointing and journaling preserve only your Helix Server metadata (data *about* your stored files). The stored files themselves (the files containing your source code) reside under `P4ROOT` and must be also be backed up as part of your regular backup procedure.
- It is best to keep journal files and checkpoints on a different hard drive or network location than the Helix Server database.
- If your users use triggers, don't use the `-f` (non-forking mode) option. To run trigger scripts, the Perforce service needs to be able to "fork" (spawn copies of itself).
- After a hardware failure, the options required for restoring your metadata from your checkpoint and journal files can vary, depending on whether data was corrupted.
- Because restorations from backups involving loss of files under `P4ROOT` often require the journal file, we strongly recommend that the journal file reside on a separate filesystem from `P4ROOT`. This way, in the event of corruption of the filesystem containing `P4ROOT`, the journal is likely to remain accessible.
- The database upgrade option (`-xu`) can require considerable disk space. For details, see the [Release Notes](#).

Related Commands

To start the service, listening to port <code>1999</code> , with journaling enabled and written to <code>journalfile</code> .	<code>p4d -d -p 1999 -J /opt/p4d/journalfile</code>
To checkpoint a server with a non-default journal file, the <code>-J</code> option (or the environment variable <code>P4JOURNAL</code>) must match the journal file specified when the server was started.	Checkpoint with: <code>p4d -J /p4d/jfile -jc</code> or <code>P4JOURNAL=/p4d/jfile</code> <code>; export P4JOURNAL;</code> <code>p4d -jc</code>
To create a compressed checkpoint from a server with files in directory <code>P4ROOT</code> .	<code>p4d -r \$P4ROOT -z -jc</code>
To create a compressed checkpoint with a user-specified prefix of "ckp" from a server with files in directory <code>P4ROOT</code> .	<code>p4d -r \$P4ROOT -z -jc ckp</code>

To restore metadata from a checkpoint named `checkpoint.3` for a server with root directory `P4ROOT`.

```
p4d -r $P4ROOT -jr  
checkpoint.3
```

(The `-r` option must precede the `-jr` option.)

To restore metadata from a compressed checkpoint named `checkpoint.3.gz` for a server with root directory `P4ROOT`.

```
p4d -r $P4ROOT -z -  
jr checkpoint.3.gz
```

(The `-r` option must precede the `-jr` option.)

Glossary

A

access level

A permission assigned to a user to control which commands the user can execute. See also the 'protections' entry in this glossary and the 'p4 protect' command in the P4 Command Reference.

admin access

An access level that gives the user permission to privileged commands, usually super privileges.

APC

The Alternative PHP Cache, a free, open, and robust framework for caching and optimizing PHP intermediate code.

archive

1. For replication, versioned files (as opposed to database metadata). 2. For the 'p4 archive' command, a special depot in which to copy the server data (versioned files and metadata).

atomic change transaction

Grouping operations affecting a number of files in a single transaction. If all operations in the transaction succeed, all the files are updated. If any operation in the transaction fails, none of the files are updated.

avatar

A visual representation of a Swarm user or group. Avatars are used in Swarm to show involvement in or ownership of projects, groups, changelists, reviews, comments, etc. See also the "Gravatar" entry in this glossary.

B

base

The file revision, in conjunction with the source revision, used to help determine what integration changes should be applied to the target revision.

binary file type

A Helix Server file type assigned to a non-text file. By default, the contents of each revision are stored in full, and file revision is stored in compressed format.

branch

(noun) A set of related files that exist at a specific location in the Perforce depot as a result of being copied to that location, as opposed to being added to that location. A group of related files is often referred to as a codeline. (verb) To create a codeline by copying another codeline with the 'p4 integrate', 'p4 copy', or 'p4 populate' command.

branch form

The form that appears when you use the 'p4 branch' command to create or modify a branch specification.

branch mapping

Specifies how a branch is to be created or integrated by defining the location, the files, and the exclusions of the original codeline and the target codeline. The branch mapping is used by the integration process to create and update branches.

branch view

A specification of the branching relationship between two codelines in the depot. Each branch view has a unique name and defines how files are mapped from the originating codeline to the target codeline. This is the same as branch mapping.

broker

Helix Broker, a server process that intercepts commands to the Helix Server and is able to run scripts on the commands before sending them to the Helix Server.

C

change review

The process of sending email to users who have registered their interest in changelists that include specified files in the depot.

changelist

A list of files, their version numbers, the changes made to the files, and a description of the changes made. A changelist is the basic unit of versioned work in Helix Server. The changes specified in the changelist are not stored in the depot until the changelist is submitted to the depot. See also atomic change transaction and changelist number.

changelist form

The form that appears when you modify a changelist using the 'p4 change' command.

changelist number

An integer that identifies a changelist. Submitted changelist numbers are ordinal (increasing), but not necessarily consecutive. For example, 103, 105, 108, 109. A pending changelist number might be assigned a different value upon submission.

check in

To submit a file to the Helix Server depot.

check out

To designate one or more files for edit.

checkpoint

A backup copy of the underlying metadata at a particular moment in time. A checkpoint can recreate db.user, db.protect, and other db.* files. See also metadata.

classic depot

A repository of Helix Server files that is not streams-based. The default depot name is depot. See also default depot and stream depot.

client form

The form you use to define a client workspace, such as with the 'p4 client' or 'p4 workspace' commands.

client name

A name that uniquely identifies the current client workspace. Client workspaces, labels, and branch specifications cannot share the same name.

client root

The topmost (root) directory of a client workspace. If two or more client workspaces are located on one machine, they should not share a client root directory.

client side

The right-hand side of a mapping within a client view, specifying where the corresponding depot files are located in the client workspace.

client workspace

Directories on your machine where you work on file revisions that are managed by Helix Server. By default, this name is set to the name of the machine on which your client workspace is located, but it can be overridden. Client workspaces, labels, and branch specifications cannot share the same name.

code review

A process in Helix Swarm by which other developers can see your code, provide feedback, and approve or reject your changes.

codeline

A set of files that evolve collectively. One codeline can be branched from another, allowing each set of files to evolve separately.

comment

Feedback provided in Helix Swarm on a changelist, review, job, or a file within a changelist or review.

commit server

A server that is part of an edge/commit system that processes submitted files (checkins), global workspaces, and promoted shelves.

conflict

1. A situation where two users open the same file for edit. One user submits the file, after which the other user cannot submit unless the file is resolved. 2. A resolve where the same line is changed when merging one file into another. This type of conflict occurs when the comparison of two files to a base yields different results, indicating that the files have been changed in different ways. In this case, the merge cannot be done automatically and must be resolved manually. See file conflict.

copy up

A Helix Server best practice to copy (and not merge) changes from less stable lines to more stable lines. See also merge.

counter

A numeric variable used to track variables such as changelists, checkpoints, and reviews.

CSRF

Cross-Site Request Forgery, a form of web-based attack that exploits the trust that a site has in a user's web browser.

D

default changelist

The changelist used by a file add, edit, or delete, unless a numbered changelist is specified. A default pending changelist is created automatically when a file is opened for edit.

deleted file

In Helix Server, a file with its head revision marked as deleted. Older revisions of the file are still available. In Helix Server, a deleted file is simply another revision of the file.

delta

The differences between two files.

depot

A file repository hosted on the server. A depot is the top-level unit of storage for versioned files (depot files or source files) within a Helix Core Server. It contains all versions of all files ever submitted to the depot. There can be multiple depots on a single installation.

depot root

The topmost (root) directory for a depot.

depot side

The left side of any client view mapping, specifying the location of files in a depot.

depot syntax

Helix Server syntax for specifying the location of files in the depot. Depot syntax begins with: `//depot/`

diff

(noun) A set of lines that do not match when two files are compared. A conflict is a pair of unequal diffs between each of two files and a base. (verb) To compare the contents of files or file revisions. See also conflict.

donor file

The file from which changes are taken when propagating changes from one file to another.

E

edge server

A replica server that is part of an edge/commit system that is able to process most read/write commands, including 'p4 integrate', and also deliver versioned files (depot files).

exclusionary access

A permission that denies access to the specified files.

exclusionary mapping

A view mapping that excludes specific files or directories.

F

file conflict

In a three-way file merge, a situation in which two revisions of a file differ from each other and from their base file. Also, an attempt to submit a file that is not an edit of the head revision of the file in the depot, which typically occurs when another user opens the file for edit after you have opened the file for edit.

file pattern

Helix Server command line syntax that enables you to specify files using wildcards.

file repository

The master copy of all files, which is shared by all users. In Helix Server, this is called the depot.

file revision

A specific version of a file within the depot. Each revision is assigned a number, in sequence. Any revision can be accessed in the depot by its revision number, preceded by a pound sign (#), for example testfile#3.

file tree

All the subdirectories and files under a given root directory.

file type

An attribute that determines how Helix Server stores and diffs a particular file. Examples of file types are text and binary.

fix

A job that has been closed in a changelist.

form

A screen displayed by certain Helix Server commands. For example, you use the change form to enter comments about a particular changelist to verify the affected files.

forwarding replica

A replica server that can process read-only commands and deliver versioned files (depot files). One or more replicate servers can significantly improve performance by offloading some of the master server load. In many cases, a forwarding replica can become a disaster recovery server.

G

Git Fusion

A Perforce product that integrates Git with Helix, offering enterprise-ready Git repository management, and workflows that allow Git and Helix Server users to collaborate on the same projects using their preferred tools.

graph depot

A depot of type graph that is used to store Git repos in the Helix Server. See also Helix4Git.

Gravatar

gravatar.com is a third party service that you can subscribe to, gravatar enables you to upload an image that you can use in Swarm. When configured, Swarm will attempt to fetch your avatar from gravatar.com and use it within Swarm. If your avatar is not found on gravatar.com, Swarm will use one of its own default avatars to represent your activity. See also the "avatar" entry in this glossary.

group

A feature in Helix Server that makes it easier to manage permissions for multiple users.

H

have list

The list of file revisions currently in the client workspace.

head revision

The most recent revision of a file within the depot. Because file revisions are numbered sequentially, this revision is the highest-numbered revision of that file.

Helix Server

The Helix Server depot and metadata; also, the program that manages the depot and metadata, also called Helix Core Server.

Helix TeamHub

A Perforce management platform for code and artifact repository. TeamHub offers built-in support for Git, SVN, Mercurial, Maven, and more.

Helix4Git

Perforce solution for teams using Git. Helix4Git offers both speed and scalability and supports hybrid environments consisting of Git repositories and 'classic' Helix Server depots.

I

iconv

iconv is a PHP extension that performs character set conversion, and is an interface to the GNU libiconv library.

integrate

To compare two sets of files (for example, two codeline branches) and determine which changes in one set apply to the other, determine if the changes have already been propagated, and propagate any outstanding changes from one set to another.

J

job

A user-defined unit of work tracked by Helix Server. The job template determines what information is tracked. The template can be modified by the Helix Server system administrator. A job describes work to be done, such as a bug fix. Associating a job with a changelist records which changes fixed the bug.

job daemon

A job daemon is a program that checks the Helix Server machine daily to determine if any jobs are open. If so, the daemon sends an email message to interested users, informing them the number of jobs in each category, the severity of each job, and more.

job specification

A form describing the fields and possible values for each job stored in the Helix Server machine.

job view

A syntax used for searching Helix Server jobs.

journal

A file containing a record of every change made to the Helix Server's metadata since the time of the last checkpoint. This file grows as each Helix Server transaction is logged. The file should be automatically truncated and renamed into a numbered journal when a checkpoint is taken.

journal rotation

The process of renaming the current journal to a numbered journal file.

journaling

The process of recording changes made to the Helix Server's metadata.

L

label

A named list of user-specified file revisions.

label view

The view that specifies which filenames in the depot can be stored in a particular label.

lazy copy

A method used by Helix Server to make internal copies of files without duplicating file content in the depot. A lazy copy points to the original versioned file (depot file). Lazy copies minimize the consumption of disk space by storing references to the original file instead of copies of the file.

license file

A file that ensures that the number of Helix Server users on your site does not exceed the number for which you have paid.

list access

A protection level that enables you to run reporting commands but prevents access to the contents of files.

local depot

Any depot located on the currently specified Helix Server.

local syntax

The syntax for specifying a filename that is specific to an operating system.

lock

1. A file lock that prevents other clients from submitting the locked file. Files are unlocked with the 'p4 unlock' command or by submitting the changelist that contains the locked file. 2. A database lock that prevents another process from modifying the database db.* file.

log

Error output from the Helix Server. To specify a log file, set the P4LOG environment variable or use the p4d -L flag when starting the service.

M

mapping

A single line in a view, consisting of a left side and a right side that specify the correspondences between files in the depot and files in a client, label, or branch. See also workspace view, branch view, and label view.

MDS checksum

The method used by Helix Server to verify the integrity of versioned files (depot files).

merge

1. To create new files from existing files, preserving their ancestry (branching). 2. To propagate changes from one set of files to another. 3. The process of combining the contents of two conflicting file revisions into a single file, typically using a merge tool like P4Merge.

merge file

A file generated by the Helix Server from two conflicting file revisions.

metadata

The data stored by the Helix Server that describes the files in the depot, the current state of client workspaces, protections, users, labels, and branches. Metadata includes all the data stored in the Perforce service except for the actual contents of the files.

modification time or modtime

The time a file was last changed.

MPM

Multi-Processing Module, a component of the Apache web server that is responsible for binding to network ports, accepting requests, and dispatch operations to handle the request.

N

nonexistent revision

A completely empty revision of any file. Syncing to a nonexistent revision of a file removes it from your workspace. An empty file revision created by deleting a file and the `#none` revision specifier are examples of nonexistent file revisions.

numbered changelist

A pending changelist to which Helix Server has assigned a number.

O

opened file

A file that you are changing in your client workspace that is checked out. If the file is not checked out, opening it in the file system does not mean anything to the versioning engineer.

owner

The Helix Server user who created a particular client, branch, or label.

P

p4

1. The Helix Core Server command line program. 2. The command you issue to execute commands from the operating system command line.

p4d

The program that runs the Helix Server; p4d manages depot files and metadata.

P4PHP

The PHP interface to the Helix API, which enables you to write PHP code that interacts with a Helix Server machine.

PECL

PHP Extension Community Library, a library of extensions that can be added to PHP to improve and extend its functionality.

pending changelist

A changelist that has not been submitted.

project

In Helix Swarm, a group of Helix Server users who are working together on a specific codebase, defined by one or more branches of code, along with options for a job filter, automated test integration, and automated deployment.

protections

The permissions stored in the Helix Server's protections table.

proxy server

A Helix Server that stores versioned files. A proxy server does not perform any commands. It serves versioned files to Helix Server clients.

R

RCS format

Revision Control System format. Used for storing revisions of text files in versioned files (depot files). RCS format uses reverse delta encoding for file storage. Helix Server uses RCS format to store text files. See also reverse delta storage.

read access

A protection level that enables you to read the contents of files managed by Helix Server but not make any changes.

remote depot

A depot located on another Helix Server accessed by the current Helix Server.

replica

A Helix Server that contains a full or partial copy of metadata from a master Helix Server. Replica servers are typically updated every second to stay synchronized with the master server.

repo

A graph depot contains one or more repos, and each repo contains files from Git users.

resolve

The process of resolving a file after the file is resolved and before it is submitted.

resolve

The process you use to manage the differences between two revisions of a file. You can choose to resolve conflicts by selecting the source or target file to be submitted, by merging the contents of conflicting files, or by making additional changes.

reverse delta storage

The method that Helix Server uses to store revisions of text files. Helix Server stores the changes between each revision and its previous revision, plus the full text of the head revision.

revert

To discard the changes you have made to a file in the client workspace before a submit.

review access

A special protections level that includes read and list accesses and grants permission to run the p4 review command.

review daemon

A review daemon is a program that periodically checks the Helix Server machine to determine if any changelists have been submitted. If so, the daemon sends an email message to users who have subscribed to any of the files included in those changelists, informing them of changes in files they are interested in.

revision number

A number indicating which revision of the file is being referred to, typically designated with a pound sign (#).

revision range

A range of revision numbers for a specified file, specified as the low and high end of the range. For example, `myfile#5,7` specifies revisions 5 through 7 of `myfile`.

revision specification

A suffix to a filename that specifies a particular revision of that file. Revision specifiers can be revision numbers, a revision range, change numbers, label names, date/time specifications, or client names.

RPM

RPM Package Manager is a tool, and package format, for managing the installation, updates, and removal of software packages for Linux distributions such as Red Hat Enterprise Linux, the Fedora Project, and the CentOS Project.

S

server data

The combination of server metadata (the Helix Server database) and the depot files (your organization's versioned source code and binary assets).

server root

The topmost directory in which `p4d` stores its metadata (`db.*` files) and all versioned files (depot files or source files). To specify the server root, set the `P4ROOT` environment variable or use the `p4d -r` flag.

service

In the Helix Core Server, the shared versioning service that responds to requests from Helix Server client applications. The Helix Server (`p4d`) maintains depot files and metadata describing the files and also tracks the state of client workspaces.

shelve

The process of temporarily storing files in the Helix Server without checking in a changelist.

status

For a changelist, a value that indicates whether the changelist is new, pending, or submitted. For a job, a value that indicates whether the job is open, closed, or suspended. You can customize job

statuses. For the 'p4 status' command, by default the files opened and the files that need to be reconciled.

stream

A branch with additional intelligence that determines what changes should be propagated and in what order they should be propagated.

stream depot

A depot used with streams and stream clients.

submit

To send a pending changelist into the Helix Server depot for processing.

super access

An access level that gives the user permission to run every Helix Server command, including commands that set protections, install triggers, or shut down the service for maintenance.

symlink file type

A Helix Server file type assigned to symbolic links. On platforms that do not support symbolic links, symlink files appear as small text files.

sync

To copy a file revision (or set of file revisions) from the Helix Server depot to a client workspace.

T

target file

The file that receives the changes from the donor file when you integrate changes between two codelines.

text file type

Helix Server file type assigned to a file that contains only ASCII text, including Unicode text. See also binary file type.

theirs

The revision in the depot with which the client file (your file) is merged when you resolve a file conflict. When you are working with branched files, theirs is the donor file.

three-way merge

The process of combining three file revisions. During a three-way merge, you can identify where conflicting changes have occurred and specify how you want to resolve the conflicts.

trigger

A script automatically invoked by Helix Server when various conditions are met. (See Helix Core Server Administrator Guide: Fundamentals on "Using triggers to customize behavior".)

two-way merge

The process of combining two file revisions. In a two-way merge, you can see differences between the files.

typemap

A table in Helix Server in which you assign file types to files.

U

user

The identifier that Helix Server uses to determine who is performing an operation.

V

versioned file

Source files stored in the Helix Server depot, including one or more revisions. Also known as a depot file or source file. Versioned files typically use the naming convention 'filenamev' or '1.changelist.gz'.

view

A description of the relationship between two sets of files. See workspace view, label view, branch view.

W

wildcard

A special character used to match other characters in strings. The following wildcards are available in Helix Server: * matches anything except a slash; ... matches anything including slashes; %%0 through %%9 is used for parameter substitution in views.

workspace

See client workspace.

workspace view

A set of mappings that specifies the correspondence between file locations in the depot and the client workspace.

write access

A protection level that enables you to run commands that alter the contents of files in the depot. Write access includes read and list accesses.

X

XSS

Cross-Site Scripting, a form of web-based attack that injects malicious code into a user's web browser.

Y

yours

The edited version of a file in your client workspace when you resolve a file. Also, the target file when you integrate a branched file.

License Statements

To get a listing of the third-party software licenses that Helix Core Server uses, at the command line, type the `p4 help legal` command.

To get a listing of the third-party software licenses that the local client (such as P4V) uses, at the command line, type the `p4 help -l legal` command.
